

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Railway Mechanical Engineer

VOLUME 94, NUMBER 1

New York—JANUARY, 1920—Chicago

ESTABLISHED IN 1832

Published Monthly by Simmons-Boardman Publishing Co., Woolworth Building, New York, N. Y. Subscription price, United States, Canada and Mexico, \$2.00 a year; foreign countries, \$3.00 a year. Entered as second-class matter, January 27, 1916, at the post office at New York, N. Y., under the Act of March 3, 1879.

NEW YARD POWER FROM OLD

Shortage of yard power can be overcome by applying Superheaters to existing yard engines.

Four and sometimes three superheated yard engines accomplish the same work as five saturated engines of similar size.

They do this because they are much quicker in starting and switch more cars; they use less coal and water, eliminating considerable dead time around coal and water stations.

Make a 24-hour running record of your yard power and compare Superheated with Saturated engines.

The results convince.

Pouring High Speed Steel Ingots

for

MOHAWK EXTRA

ELECTRIC CRUCIBLE STEEL

This illustration shows a general view of our melting and pouring room. Six large Ludlum Electric Furnaces in the background, and one of our ladles and carriages busily at work in the foreground.

With this equipment to take care of the first operation in the production of Mohawk Extra High Speed Steels, we are able to reach an output of over 250 tons a month.

Ludlum Steel "Consistently Uniform"
BRANDS:

Mohawk Extra High Speed Steel	Pompton Carbon Tool Steel
Albany Alloy Tool Steel	Oneida Oil Hardening Steel
Huron Alloy Die Steel	Teton Ball Bearing Steel
Yuma Chrome Magnet Steel	Seminole "Foolproof" Chisel Steel

Prompt shipments from warehouse stock at Watervliet, N. Y., or Detroit, Mich., Chicago, Ill., and Cambridge, Mass.—handled through our District Offices.

The first story entered in the *Railway Mechanical Engineer's* prize story contest is published in this issue. Before the closing date of the competition we hope to receive many more articles. No doubt practically all of our readers have very definite ideas as to the problems the mechanical department is facing. While the actual conditions often cannot be set forth for various reasons—this story contest gives an opportunity for bringing out the problems and pointing the way to their solution.

Have You Written That Story?

Read the story in this issue and then write up some of your own experiences. If the story is published it will be paid for at our regular space rates. In addition the authors of the three best stories will receive prizes of \$75, \$50 and \$25. The use of good English and the literary finish will of course be considered in awarding the prizes, but far more importance will be attached to the ideas brought out, the portrayal of the characters, the reproduction of the railroad atmosphere and the development of the plot. You still have more than two months to send in your contribution, but don't put it off until the last minute. Sit down tonight and see whether you can't write a story that will take one of the prizes.

The locomotive front end in its present state of development is a crude affair, designed and regulated as it is on a "rule of thumb" basis. There is probably

Hands Off the Draft Appliances

no other part of the locomotive concerning the operation and adjustment of which so many theories are held, the most creditable of which are founded on a very small amount of fact. The general attitude is that one guess is as good as another and every one, from the fireman up, feels perfectly justified in putting into practice

his own ideas whenever opportunity permits. Imperfect as they are, however, there must be some arrangement of the draft appliances on each class of locomotive which, with the least amount of back pressure, will produce a free steaming locomotive. The discovery of this arrangement involves no great difficulty, and when once found there is no reason why it should not apply to every locomotive of the same class.

There are probably few railroads in the country today that have adopted or maintain rigid standards of front-end arrangement. This results in a loss of motive power capacity as well as efficiency. These losses are due to improper adjustments of the draft appliances themselves, such as a restricted opening under the deflector plate, the effects of which are overcome by the use of a nozzle opening small enough to force the locomotive to steam, or defects in other parts of the locomotive, failure from which may be prevented by front-end adjustments.

Unfortunately, within comparatively wide limits other defects may be overcome at the nozzle, but the result is a waste of fuel and the loss of capacity due to excessive back pressure from restricted nozzle area, which has been found in tests conducted by the Fuel Conservation Section to be as great as 10 to 20 per cent in the possible ton-mile per hour output of the locomotive. In this connection, air leaks around outside steam pipes were found to cause an increase in fuel consumption as high as 30 per cent. In such cases, when the remedy is applied at the nozzle, the real difficulty is not corrected; it is merely concealed and permitted to grow as a potential cause of complete failure.

When a standard front-end arrangement has once been established unauthorized changes should not be permitted, and traveling engineers, fuel supervisors and front-end inspectors should all be charged with the duty of reporting immediately any variations from standard which they may discover. When an engine is reported not steaming the real

cause of the difficulty should be located at once and the correct remedy applied. The presumption should always be that the draft appliances never are the cause unless they are found to vary from the standard.

There is no longer any real necessity for providing for adjustments in the front end. If variations from the established standard are to be prohibited the obvious course is to remove as far as possible all temptation to tinker with the draft appliances and the parts should be put in place permanently. This at least will remove the opportunity to change the deflector plates and draft pipes, leaving the nozzle alone, to be taken care of by the adoption and vigorous execution of a policy of "Hands Off."

There have been notable improvements in the design of refrigerator cars during the past few years and the transportation of perishable products is now receiving more general attention than at any time in the past. For that reason the report of comparative tests of refrigerator cars with two different arrangements of ice receptacles, published in this issue, is of particular interest. In the tests the car equipped with the overhead bunker showed a marked saving in ice consumption and also a lower temperature range throughout the load than the car with end bunkers. It is difficult to determine how much of this saving can be attributed to the overhead ice bunker and how much is due to other differences in the construction of the cars. The insulation in both cases was practically the same, but the Chicago Great Western car was equipped with floor racks, while the Santa Fe car did not have them. There can be no doubt that the free circulation of air resulting from the use of floor racks was largely responsible for the more uniform temperature existing in the Chicago Great Western car, although the location of the ice near the top of the car should prove advantageous in promoting the circulation, particularly when the supply of ice becomes low. Whether a part of the saving in ice is also due to the use of the floor racks can hardly be determined. The data presented in the report is interesting and in view of the decided difference in the results obtained, it is to be hoped that additional comparative tests of end bunkers and overhead bunkers will be conducted with cars which are otherwise identical in construction.

Testing Refrigerator Cars

One of the significant facts brought out in the report of the chief inspector of locomotive boilers, an abstract of which appeared in the December issue, is the large increase in the number of accidents caused by arch tube and washout plugs. As compared with the fiscal year 1918, the number has more than doubled, and it is almost 50 per cent greater than the largest number reported during any previous year. The history of this cause of accidents is interesting. Beginning with 1912, when the number of accidents due to plugs was 13, the next two years showed an increase to 20 and 21, respectively, followed by a reduction in 1915 to 16, with practically no change in 1916, and a further material decrease to 8 in 1917. In 1918 there were 14 accidents reported, and during the past year the number was 30.

Accidents Due to Washout Plugs

What conclusions may be drawn from these facts? Probably the only definite conclusion justified by the facts presented is that war conditions have been responsible for the increases in 1918 and 1919—probably by increasing the amount of untrained and inferior labor used for washing out boilers. But that alone is strong evidence of the small margin of safety existing under the best of conditions in the

use of these plugs. They must, of necessity, be fitted with threads disproportionately fine by comparison with their diameter, making it always a delicate operation to start the plug in the sheet without crossing the threads. When cross threaded the plugs usually leak. Under such conditions, considerations of safety are largely overbalanced by the pressing necessity for keeping the locomotive in service, and almost invariably an attempt is made to tighten the plug to stop the leak. The only other alternative is to take the engine out of service and cool it down in order that the plug may be removed and properly applied.

It seems evident that there is but one adequate remedy for this class of accidents; that is the elimination of the screwed plug and the substitution of some form of handhold plate to close the arch tube and washout openings in the boiler sheets. The number of accidents due to the failure of these plugs does not place them among the most serious sources of casualties, considering as a whole the years during which the boiler inspection law has been in operation, but the erratic nature of the results from year to year, together with the heavy increase in accidents from this source during the past year are sufficient evidence of the inherent danger involved in the use of the screw plug. The removal of this danger is a matter for the attention of the designer. Let him accept the responsibility.

The communication on how to increase production, which appears on another page, indicates clearly the necessity of improving the morale throughout all departments of the railroad service. The railroads, like the greater number of industrial concerns, have made a serious mistake in the past in not taking more positive steps to acquaint their employees as to the problems, large or small, with which they have been confronted and as to the actual financial condition of the properties.

The Next Step

Railroad employees have consistently demanded better working conditions and higher wages. It is rather strange to find, however, that the labor unions have consistently fought increases of rates and have advocated some very peculiar legislation which would prove most detrimental to the railroads from a financial standpoint and would not give any real advantages to the men. The shippers and the public itself have not gone to any greater extremes in accusing the railroad executives of mismanagement. Investigation of most of these accusations has shown that the wrongdoings, if there were any, occurred many years ago and have been entirely wiped out by improvements to the property which have since been made from earnings; moreover, the conditions under which the roads have operated for a number of years have made anything of this sort impossible. It would seem, therefore, that because of the mutual interests of the men and the managements the men would be glad to co-operate with the railroads in pleading their case before the public.

Is it not true that the managements should adopt far more positive and aggressive methods than they have in the past to acquaint their employees fully with the exact conditions of the properties, financially and otherwise? There is no one way of accomplishing this. If real results are to be obtained all of the officers and foremen, and particularly those who come in direct contact with the men, must unite in conducting a campaign of publicity and education that will place the real facts before the men. This important responsibility up to this time has apparently been overlooked on most roads because those in charge did not realize its importance. Immediate steps should be taken to improve the situation and thereby bring up the entire morale of the service.

The spirit of the letter above referred to should be kept constantly in mind. Improved facilities, better tools and more efficient equipment are all well as far as they go, but the most vital factor in securing greater efficiency or increased production is to improve the morale of the forces.

Fuel cost the railroads of the United States approximately \$290,000,000 for the year ending June 30, 1914; for the year just closed the expenditure for this item was in excess of \$600,000,000. With the fuel bill more than doubled, the number of passenger car miles was practically the same for the two years

**Why a
Fuel
Department?**

and the increase in revenue ton miles was not in excess of 40 per cent. Furthermore, the number of revenue tons per train increased from 460 in 1914 to nearly 700 in 1919, a factor exerting a tremendous influence in favor of reduced unit coal consumption. The growing importance of the fuel bill is evident and no railroad can afford not to take effective measures to prevent waste in this expenditure. No doubt, this is generally recognized but the requirements for preventing it are far less generally recognized.

The maximum return from the money spent in the purchase of fuel can only be obtained where there is definite responsibility in some department for the selection, acceptance, storage, distribution and consumption of fuel. A review of the history of the progress of fuel from the mine to the firebox shows that to none of the established departments is the conservation of fuel of more than secondary importance. The selection and purchase of fuel is under the jurisdiction of the purchasing agent, whose interest and responsibility is primarily in securing the best possible price per ton. Whether the quality of the fuel receives adequate attention depends largely on his personality. The storage and distribution of the fuel may be left in the hands of the stores department, the operating department or the mechanical department. Its final use in the firebox is in the hands of the enginemen and firemen with such supervision as the road foreman can give to this matter along with his numerous other duties and assignments. If the fuel is distributed through the purchasing and stores department, the responsibility of these departments ends with the receipt of coal tickets in sufficient amount to effect an approximate bookkeeping balance. With the distribution in the hands of either the operating or mechanical departments, there is much the same opportunity for a shift of responsibility between the coal chute and the firebox because economy in the final use of the fuel is a matter for which neither department alone is responsible.

The main object of the operating department is to get trains over the road, maintaining passenger schedules and keeping the line clear of tonnage and, with the condition of power in the hands of the mechanical department, consideration of economy does not usually go beyond the questions of overtime for crews in appraising the success of this effort. The success of the mechanical department is likely to be measured on the basis of the number of engine failures, little attention being given primarily to obtaining from the locomotives their highest overall efficiency. The road foreman of engines is responsible for the operation of the locomotives; he is also responsible for many matters pertaining to the operating rules and not infrequently is burdened with office duties which leave him little time for the consideration of the locomotive beyond cases of actual failure. None of these departments is responsible for fuel conservation and none is aware of the constant waste which may be taking place daily through the divided and easily shifted responsibility.

The only solution of this problem is the centralization of fuel control in a staff department, the primary purpose of which is to find the leaks and initiate proper practices to stop them.

Much has been done by the Fuel Conservation Section of

the Railroad Administration in demonstrating the correctness of the principle of organized fuel control. As compared with 1918, during the past year, on the basis of unit consumption, a saving approaching \$40,000,000 has been effected by measures almost entirely within the control of the managements of the railroads of the United States. This is partially the result of the organization of fuel departments on a number of roads not previously having them and partly due to the efforts inspired by the Fuel Conservation Section.

The results from the latter cause are only temporary. If the work of the Fuel Conservation Section is allowed to lapse with the return of the railroads to private operation, there will be a reaction from the inspired effort put forth during the war. Interest in the matter will be lost and wasteful practices in the handling and use of fuel so common before the war, will re-establish themselves. Inspiration is of value only so long as it lasts; continued results can be obtained only where definite responsibility exists.

It seems evident, therefore, that failure to continue the work of the Fuel Conservation Section beyond the term of federal control will result inevitably in the loss of much of the ground which has been gained in the general establishment of correct practices in the handling and use of fuel. The centralized control of fuel conservation measures should be continued through the reactionary period, during which time the summary of locomotive fuel performance compiled and published quarterly by the section should prove of inestimable value in keeping up the interest in fuel conservation measures, as well as in providing concrete evidence of the large return which each road may obtain by the permanent establishment of its own fuel department.

NEW BOOKS

Proceedings of the International Railway General Foremen's Association.
162 pages, 6 in. by 9 in., illustrated, bound in leather. Published by the association, William Hall, secretary, Winona, Minn.

This book contains the proceedings of the International Railway General Foremen's Association convention, held September 2-5, 1919, in the Hotel Sherman, at Chicago, Ill. The addresses delivered before the convention by R. H. Aishton, regional director of the Northwestern region, and L. A. North, president of the association, are given in full. The various papers read before the convention and the discussions of the subjects by the members are recorded and should prove to be a very valuable reference for the members at large. Among the papers read and discussed were several touching on the subject of safety first, by L. A. North, B. F. Harris and W. T. Gale. Other subjects considered were welding of locomotive cylinders, autogenous welding of locomotive parts and several papers on the design and maintenance of draft gear.

Proceedings of the American Railroad Association, Section III—Mechanical.
668 pages, 6 in. by 9 in., illustrated, bound in cloth. Published by the association, 75 Church street, New York.

This volume contains the proceedings of the American Railroad Association, Section III—Mechanical, and covers all of the matters formerly treated separately in the proceedings of the Master Car Builders' Association and the American Railway Master Mechanics' Association. Complete reports are given of the various addresses delivered at the convention by men prominent in railroad affairs, and also the reports of the numerous committees and the discussions by the members. Of particular interest are the papers relating to fuel economy, mechanical stokers, powdered fuel and welding in its various phases, as applied to both the car and locomotive fields. The book was compiled and published by the secretary of the association, V. R. Hawthorne, and covers in the usual complete manner the proceedings of the organization. As in 1918, the standard drawings are issued separately in loose-leaf form.

COMMUNICATIONS

A CORRECTION

ALLSTON, MASS.

TO THE EDITOR:

I wish to call attention to an error in the letter "Inadequate Main Driving Boxes," published in the November issue on page 630. The second line in the second paragraph should read: "that where they do hold the box as regards wedge adjustment." It was not my intention to find fault with spring adjusted wedges from the point of view that they do not do the work they were constructed to do in that respect. From my observation they do hold the wedge in adjustment.

JOHN C. MURDOCK.

DANGERS IN EMPTYING BARREL

LA CROSSE, WISCONSIN.

TO THE EDITOR:

In reading the October issue of the *Railway Mechanical Engineer* I noticed the device on page 600 for removing liquids from barrels or other containers. I had one of these connections made about six years ago and have discontinued using it because it proved to be unsafe. A helper was emptying a tank of crude oil and the pressure became excessive and blew the head out of the barrel. This might have caused a very serious accident had the helper been standing in front of the barrel, for the entire head was blown about 40 feet.

I think this may be remedied by using some kind of a safety valve connection, but otherwise the oil is liable to get stopped up and raise the pressure of the tank. I had a $\frac{3}{4}$ in. pipe for the oil outlet and $\frac{1}{4}$ in. pipe for the air. All connections were identical with those shown in your sketch.

E. WAGNER.

HOW TO INCREASE PRODUCTION

SOUTH ORANGE, N. J.

TO THE EDITOR:

Because I have always taken a keen interest in studying human nature, I firmly believe that many of the problems that confront us today could be solved if men in all walks of life would study the characters of the men who are associated with them, not only those in authority over them, but those who work under them. Apply this to the questions asked in the November issue of the *Railway Mechanical Engineer*, "What might be done to improve supervision, to put production on a better basis or take the kinks out of the organization?"

There has been such an upheaval in the management of the railroads during the past two years—old methods discarded and new methods adopted; customs (that had been in vogue so long they were considered essential to the well-being and maintenance of the road) swept aside and a complete reversal of the order of the day—that it would be a waste of time to attempt to draw comparisons between the former and the present methods, in an effort to prove which is the most effective.

Something can be done that will improve supervision, increase production, take out the so-called kinks and put every railroad in this country on a strong, healthy financial basis. It may not be accomplished in a month or a year, because confidence has been almost destroyed, because loyalty is almost a forgotten quantity, because incentive no longer exists, because not only the present methods used, but in a measure the former as well, lose sight of, or rather fail to take into account the one big factor that more than any other affects the growth and success of all organizations, namely, morale.

Every official, every man in a supervisory capacity, every employee must be made to feel that the success or failure of the road is largely dependent on his own individual effort. Create this spirit and you will restore confidence, beget loyalty and incentive, will again inspire new life.

No matter what station in life is yours, if you want success you must be absolutely just in your treatment of those associated with you. Be a big man, play the game fair, be big enough to lay aside petty jealous feelings and selfish motives; when matters arise that affect the interest of others, take them into your confidence and your councils. Bend every energy to produce and promote and the wheels of progress that seem almost to have stopped will revolve again.

Let's start.

H. L. JACKSON.

THE COLLEGE MAN IN RAILROAD WORK

URBANA, ILLINOIS.

TO THE EDITOR:

From time to time you have published for the benefit of your readers discussions as to the work of the college man in a railway shop organization. Opinions have differed as to just what consideration, if any, should be made for the four years' training he has received in college, but no one heretofore has attempted to bar him from the shop entirely or to claim that the railroads would be better off without any college men whatever.

But many of us are wondering how a college graduate is going to get into a railway shop or to acquire the practical experience necessary for him to be able to use this training, provided the terms of the present shop agreement remain in effect.

As a helper, the only position the majority may enter, he can receive no training or experience. His services in an official capacity would be of no value without practical experience. By the time he completes his college course he is generally too old for a regular apprenticeship and generally in debt financially. If one of the few to complete college before passing the maximum age at which regular apprentices may be employed, even if financially able, and possessing sufficient determination to go through the regular grind for another full four-year course, he must serve the greater part of this at a rate of pay less than is paid common laborers.

Upon finishing the full apprenticeship course, and having thus spent eight years in preparation for his life work, he would then, according to the present national shop agreement, be entitled to only the poorest and least desirable job in the shop. He would have less seniority rights than the most ignorant or least ambitious boomer who might have entered the shop the day before the college man completed his apprenticeship, the eighth year of his training. Though the latter might not know an indicator card from a dress pattern, or have no conception of the use to which the job assigned him is to be put, no knowledge of the reason for its design or construction, or of the importance of its being finished accurately or with dispatch, he would have preference in the selection of any job in the shop over this man whose four years of college training had been supplemented by an equal period of practical experience in the very shop where he had already worked practically four years before the boomer happened to light. Would anyone call this a square deal? Or does it offer sufficient inducement to the young man desiring to fit himself for railroad work to enter college to better prepare himself for such work?

We do not know whether the situation in which the college man is thus placed was brought about intentionally or otherwise. But if education means anything at all, if there is any place whatever for the college man in a railway shop organization, some provision must be made to give him the opportunity denied him under the present national shop agreement.

"THE COLLEGE MAN."

RAILROADS' MECHANICAL FACILITIES INADEQUATE

Growing Traffic Cannot Be Handled Without Additional Equipment, Estimate of Needs for Next Three Years

SIX billion dollars is the amount that should be spent in the next three years to provide facilities which the railroads will require to handle properly the growing traffic of this country, according to the estimate of the Railway Age. Of this amount nearly \$2,000,000,000 should be spent for freight cars, \$600,000,000 for passenger cars, \$900,000,000 for locomotives, and \$150,000,000 for shop and enginehouse equipment.

OTHER FACILITIES

In addition to the rolling stock and shop equipment needed, the Railway Age estimates that the roads should acquire within the next three years 6,000 miles of new tracks at a cost of \$600,000,000; revisions of grades, cut-offs and the elimination of curvature, costing \$600,000,000; 15,000 miles of new multiple main tracks at a cost of \$1,250,000,000; new station buildings costing \$300,000, and 10,850 miles of automatic block signals costing \$52,000,000.

FREIGHT CARS

There has been serious shortage of freight cars since 1916, except for a few months after the signing of the armistice. The traffic during the last four years has been very heavy, but at present is not greatly in excess of what might be expected under ordinary conditions. The normal traffic for the next six years has been estimated as follows:

	Ton-miles
1920.....	378,075,000,000
1921.....	393,815,000,000
1922.....	410,125,000,000
1923.....	427,030,000,000
1924.....	444,540,000,000
1925.....	462,700,000,000
1926.....	481,515,000,000

It is probable, however, that the traffic will remain abnormally high for some time to come, and it is estimated that the actual traffic in 1920 will be 410,000,000,000 ton-miles; in 1921, 418,000,000,000 ton-miles, and in 1912, 427,000,000,000 ton-miles.

In order to determine how many cars would be required to move this traffic, a study of the number of ton-miles carried per year for each ton of car capacity was made. This showed that the ton-miles per ton of capacity per year has been in excess of 3,500 for the yearly period whenever there has been a car shortage, and has been below 3,500 whenever there was an ample supply of cars. This indicates that one ton of freight car capacity should be provided for every 3,500 tons to be moved during the year. This was actually the case from 1905 to 1915, but the number of cars built in recent years has been abnormally small, and since 1914 there

has not been a single year when the railroads have bought enough new cars to take care of the normal increase in traffic.

The Class I roads in 1918 had 2,323,324 freight cars, with an aggregate capacity of approximately 97,000,000 tons. The increase in capacity during 1919 has probably not been more than 1,500,000 tons, making the present capacity 98,500,000 tons. As Class II and Class III roads own about 2.7 per cent of all railroad freight cars, this capacity must be increased by that amount to make it comparable with the statistics of traffic. This would bring the total capacity for all roads to 101,100,000 tons. Under normal conditions this capacity would be sufficient to handle an annual traffic of 354,000,000,000 ton-miles, but since the traffic in 1919 will amount to about 400,000,000,000 ton-miles it is evident that there is not enough equipment to handle it in a satisfactory manner. On the basis of 3,500 ton-miles per ton of capacity per year, the present traffic would require a car capacity of 114,200,000 tons, or about 13,100,000 tons more than is now available. As the average capacity of cars now built is 50 tons, this would indicate that 262,000 additional cars must be provided to make up for the present shortage.

Assuming that business will increase at a constant rate and will reach the normal in 1924, the annual increase will amount to 8,108,000,000 ton-miles, which would require a capacity of 2,320,000 tons. Assuming that the average capacity of the cars built will increase to 55 tons, this would require 42,000 cars. This is not representative of the number that would ordinarily be needed to care for the increase in the traffic, because the present traffic is high, and therefore the assumed rate of increase for the next three years has been made correspondingly low. Under normal conditions about 100,000 cars would be needed to provide for the increase in traffic.

Aside from the question of providing for the traffic, there remains the need for retiring old equipment from service. As the demand for freight cars has been greater than the supply for more than three years, cars have been kept in service whenever it was possible and the number retired has been very low. Statistics indicate that the retirement of 120,000 cars which would naturally have been scrapped during the past three years has been deferred. The Railroad Administration has stated that of the 150,133 cars bad order on the fifteenth of November 19,300 were held out of service as not worth repairing. This is certainly a minimum figure. The deferred retirements amount to at least 100,000 cars, and although some of the box cars may be worth reinforcing

and returning to service, not less than 75,000 cars should be scrapped.

The report of the Interstate Commerce Commission for December 31, 1917, showed that at that time the Class I carriers still had in service 904,007 freight cars not of all-steel or steel underframe construction. Until these light wooden cars have been scrapped the rate of retirement should certainly not be less than 120,000 cars per year. Assuming that 25 per cent of this equipment can be reinforced, there still remain 90,000 old cars to be destroyed during each of the next three years. The average capacity of the cars scrapped will be approximately 33 tons and the capacity of new cars 50 tons. Therefore, to replace the equipment ton for ton would require:

	Cars
For deferred retirements.....	49,500
For normal retirements.....per year	58,300

SUMMARY

Summing up the cars needed to make up deficiencies, to provide for future increases and to take care of retirements, the total amount of equipment required during the next three years is found to be as follows:

	Cars
To make up the present shortage.....	262,000
To provide an adequate surplus.....	100,000
To take care of increases in traffic.....	126,000
To make up for deferred retirement.....	49,500
To care for normal retirements.....	174,900
Total cars needed in three years.....	712,400
Annual requirements.....	237,500

The private car lines own about 200,000 freight cars and the Canadian roads have also about 200,000. If the new equipment needed by these car owners bears the same relation to the total number owned that prevails for the railroads in the United States, the car-building plants of this country and Canada should be called upon to furnish 830,000 cars during the next three years.

TYPE OF CARS THAT WILL BE BUILT

Few important innovations in freight car design have been introduced in the past decade, and the equipment built during the next few years will probably not be radically different from the types now in service. Box cars form a large percentage of the equipment and little further increase in capacity is to be expected, as the opinion seems to prevail that nothing is gained by increasing the capacity of box cars above 40 tons. In open-top equipment, however, there is a strong tendency toward the use of high-capacity units. Ninety-ton cars are by no means uncommon, and experimental cars of 105 and 110 tons' capacity have been constructed. The operating results secured with high-capacity cars have been satisfactory, and they will probably be built in greater numbers.

The unit cost of the equipment which the railroads buy in 1920 will be greatly in excess of pre-war prices. The lowest scale of prices for freight cars in recent years was that prevailing in 1914 and 1915. At that time cars could be bought for \$800 to \$900. By 1916 they had advanced to \$1,100, in 1917 to \$2,100 and in 1918 the average was about \$2,850. The prices that will prevail during 1920 will depend on the cost of materials, and cannot be predicted with any degree of certainty. Under present conditions practically the same prices that existed in 1918 apply. It is probable that the 240,000 cars that should be built this year would cost between \$670,000,000 and \$700,000,000. Assuming that present prices continue the 712,000 cars needed in the next three years will involve an expenditure of approximately \$2,000,000,000.

PASSENGER CARS

The shortage of passenger equipment at the present time is brought out strikingly by the fact that in 1919 the num-

ber of passengers per car was 31 per cent greater than the maximum during any year from 1905 to 1915. In the 10-year period ending June 30, 1915, the volume of passenger traffic on the railroads of the United States, as measured by the number of passengers carried one mile, increased 48 per cent. During this period 26,800 passenger train cars were purchased.

In the four and one-half years since June 30, 1915, the number of passengers carried one mile has increased over 43 per cent, but less than 4,000 cars have been purchased. To provide for the present volume of passenger traffic on pre-war standards of service, without allowance for retirements, would require over 18,000 more passenger train cars than the railroads now own.

During the ten calendar years ending with 1914, the Railway Age reports a total number of passenger cars ordered of approximately 22,900, of which 78 per cent were for the steam railroads of the United States. During the same period Railway Age statistics show a total of approximately 34,400 passenger cars actually built in the United States and Canada. While it is evident that the statistics for the number of cars ordered is not as complete as for the number of cars built, it is reasonable to assume that approximately the same proportion in each case were for use on the steam railroads of the United States. On this basis it is evident that the railroads must have received about 26,870 new passenger train cars during the ten years from 1905 to 1915. But during this time the actual number of cars in service increased only 14,063, and it is evident that about 12,800 cars must have been retired. The yearly average for the ten years is, therefore, 2,687 new cars purchased, of which 1,280 replaced old cars retired from service and 1,406 were added to take care of the traffic increase.

During the four and one-half years since June 30, 1915, passenger miles have increased 13,810,000,000, or 43.5 per cent. This is a larger proportionate increase than that for the ten years prior to 1915 and but slightly less than the actual maximum increase during the period from 1905 to 1914.

During the first year and one-half of this period there was actually less passenger equipment in service than at the beginning of the period, and at the end of 1917 there were only about 300 more passenger cars in service than were shown for the fiscal year 1915. For the whole period of four and one-half years, with its increase in volume of passenger business of over 43 per cent, the number of passenger cars in service increased by 2.5 per cent.

While the number of cars ordered during the four calendar years ending with 1918 was approximately 7,000, only 45 per cent of this number were for use on the steam railroads of the United States. Applying the same percentage to the approximately 7,490 cars built during the four and one-half years prior to December 31, 1919, only 3,370 passenger train cars were built for steam railroad use in the United States. As at least half of the cars built in 1915, or about 440, were probably in service prior to July 1, the beginning of the period under discussion, the number of new cars actually placed in service in the four and one-half years probably did not exceed 2,930. As the number of passenger cars in service increased but 1,310 during the period, it is evident that about 1,620 cars were retired. An average of only 652 new cars were received by the roads annually, of which 360 were replacements and 291 were additions to the passenger carrying equipment of the country.

Comparing the years up to 1918, there is evident a growing inability of the equipment available to meet the heavy increase in traffic, which is shown by the increase in the number of miles per passenger carrying car per year from 59,600 in 1915 to 66,000 in 1917, with a corresponding in-

crease in the number of passengers per car from 15.3 in 1915 to 17.6 in 1917.

In 1918 there was a sharp decrease in car mileage, due to the curtailment of service effected by the Railroad Administration. This and an increase in the number of cars in service of 961 resulted in lowering the average car miles per passenger carrying car from 66,000 to 58,600, but the number of passengers per car increased from 17.6 to 20.4, by far the largest increase ever recorded. Of course, the heavy troop movement, which was practically continuous throughout the year 1918, tended to increase this figure above that representing conditions prevailing in the handling of regular passenger business. The aggregate of this troop movement for the 22 months from January 1, 1918, to November 1, 1919, however, was 5,917,658,719 passenger miles, or only 14 per cent of the total volume of passenger business of the year 1918 alone, and can hardly have exercised a predominating influence on the average. Its effect may practically be eliminated by comparing 1917 with 1919, as the troop movement during these two years was confined to about one-half of the year in each case, and here the increase is shown to have been over three passengers per car.

The sharp decline in passenger car mileage, showing an average of 58,600 and 61,400 miles per car per year, respectively, for 1918 and 1919 following the high mileage during 1917, raises the question as to whether the change in conditions is actually due to a shortage of equipment or entirely to the war policy of the Railroad Administration. Assuming, however, that the equipment had been used to the same extent during these two years as it was during 1917, so that each passenger carrying car had averaged 66,000 miles for the year, the number of passengers per car would have increased to 18.1 in 1918 and 19.3 in 1919, clearly demonstrating that even under normal methods of handling passenger business there would still have been a rapidly growing shortage of equipment.

Passenger equipment may be divided roughly into two major classes: (1) passenger carrying cars and (2) express, baggage and postal cars. In the tables already referred to are given a clear presentation of the volume of passenger traffic and the total number of passenger carrying car miles to handle the traffic. This forms a fair basis for determining the needs for passenger carrying cars if the assumption is made that there has been no great change in the relative amount of car mileage made by equipment of railroad ownership and Pullman sleeping and parlor cars, or that there has been no material increase in the carrying capacity of passenger cars of railroad ownership. The remarkable uniformity of the number of passengers per car during the eight years prior to June 30, 1915, would indicate that these are reasonable assumptions. At the end of that period there were 10,884 passenger train cars of all-steel construction and 5,197 with steel underframes, a total in both groups of 38 per cent of the equipment in service, practically all of which had been built during that period, with no marked effect on the average car load.

Leaving out of consideration the first three years of the ten years prior to 1915, during the first two of which the number of passenger-miles per passenger carrying car was light, and considering only those years for which passenger car mileage statistics are available, it will be found that the average number of passenger-miles per passenger carrying car average about 950,000, which was equivalent to an average of about 61,500 miles per car per year with an average load of 15.4 passengers per car. To have handled the 45,060,000,000 passenger miles of passenger traffic in 1919 under these same conditions would have required a total of 48,000 passenger carrying cars, but there were only approximately 35,700 passenger carrying cars in service during that year, indicating a shortage of 12,300 cars.

But it is questionable whether passenger service should ever be restored completely to the competitive basis existing prior to 1915. It will be conservative to assume that the service should be restored to the standards of 1917, when there were 17.6 passengers carried per car movement, and it would seem reasonable to expect the maintenance of an average mileage per car throughout the country of 63,000 per year. To have handled the 45,600,000,000 passengers carried one mile in 1919 on this basis would have required 41,080 cars, which is 5,480 cars more than were actually in service.

Assuming for the next three years an annual increase of an even 2,000,000,000 passenger-miles, the railroads will be required to purchase 5,400 additional passenger carrying cars during the three-year period to maintain the standards of service and equipment mileage outlined above. It will, therefore, be necessary to purchase 10,880 passenger carrying cars during the next three years.

During 1918 the passenger carrying cars of the Class I railroads made up 66 per cent of the total number of passenger train cars in service. Assuming the continuance of this ratio, which, however, has been gradually decreasing, it will be necessary to purchase 5,620 new baggage, mail, express, dining and other passenger train cars in addition to the passenger carrying cars, which include coaches, combination passenger cars and sleeping and parlor cars of railroad ownership. Of this number about 4,800 will be baggage, mail and express cars.

During the ten years prior to 1915 there was an average retirement of 1,280 cars annually. During the last four years there has only been retired an average of 360 cars each year. It is evident, therefore, that there are 4,140 cars now in service which should be retired at the earliest opportunity, and on the same basis 3,840 more cars should be retired during the next three years. Adding these 7,980 cars to the actual increase required, it is evident that there must be purchased during the next three years a total of about 24,500 passenger train cars, or an average of 8,160 cars a year, if passenger service is to be restored to the 1917 standards.

Such data as is available indicates that the increase in prices of passenger cars which has taken place during the war period has been about 200 per cent, or in other words, that the equipment purchased now will cost approximately three times as much as the cost of similar equipment purchased in 1914. This ratio holds very closely true when applied to the prices for locomotives and freight cars paid by the Railroad Administration during 1918, and, considering the increases in prices which have taken place since, it may be considered a conservative basis on which to estimate the capital required for the purchase of new equipment. Baggage, mail and express cars costing between \$6,000 and \$7,000 in 1914 will cost on an average of \$21,000 to \$22,000 at the present time, while steel coaches which cost \$8,500 in 1914 can probably not be built at the present time for less than \$25,000 to \$26,000. Applying these prices on a weighted average basis of the proportion of these two classes of equipment to the total, a conservative price for the 24,500 cars required in the next three years may be taken at \$24,000 each.

If the railroads are to restore and maintain passenger service to the standard of 1917, an expenditure, therefore, of \$588,000,000 will be required for new equipment during that time; this is an annual average of \$196,000,000.

LOCOMOTIVES.

The motive power situation is fully as serious as the shortage of freight and passenger cars. A conservative estimate, based on the average increase in railroad traffic and in the motive power during the decade ending with the year 1914, indicates that at least 698,000,000 lb. additional tractive power should be built in the next three years.

During the period from 1905 to 1915, in addition to an

increase of 34 per cent in the number of locomotives on American railroads, there also was an increase of 71 per cent in the aggregate tractive power. Statistics of the Interstate Commerce Commission show that the average distribution of tractive power is 63.5 per cent in freight service, 20.5 per cent in passenger service, 14 per cent in switching service and two per cent unclassified. The estimates of future requirements are based on these ratios, and the small percentage of new unclassified locomotives is included with those for freight service.

In the year 1905 the freight traffic of the United States totaled 186,463,109,510 ton-miles, and this increased at a fairly constant rate until in 1914 it had reached a total of 288,319,890,210 ton-miles, an average yearly increase for the decade of 5.46 per cent. This rate of increase if continued to the end of the year 1919 would have made a total freight traffic of 388 billion ton-miles. However, the statistics of the first ten months of the year 1919 and a conservative estimate of the probable volume of business for the months of November and December indicate that the actual freight business for the year will reach the enormous total of 402 billion ton-miles. These figures for the year 1919 may be taken as a basis on which to estimate the probable freight traffic for the next three years, which will probably reach 410 billion ton-miles in 1920, 418 billion ton-miles in 1921 and the stupendous total of 427 billion ton-miles in 1922.

To handle properly this vast amount of freight in 1920 it will be necessary to have an aggregate tractive power of 1,651,000,000 lb. in freight locomotives. This will require the building of a large amount of additional motive power. New freight locomotives to be built should average about 60,000 lb. tractive effort.

The statistics of the Interstate Commerce Commission show that in the past years approximately 63.5 per cent of the total available tractive power was engaged in freight service, and on that basis 248.3 ton-miles of freight were hauled during the year for each pound of tractive power of freight locomotives. The average ton-miles per year per pound of tractive power was somewhat in excess of 248.3 in 1918 and 1919, but an average taken over the entire period of 14 years from 1905 to 1918 was only 251.1 ton-miles per year per pound of tractive power. This average is subject to fluctuation, and as will be seen in the tabulations the average ton-miles per pound of tractive effort in 1906 reached the extremely high figure of 273 ton-miles, but dropped to 235 ton-miles in 1914. It is for this reason that an average for a ten-year period during normal times is taken as a basis for calculating the work that will probably be done in the future. This average may be improved upon, but there is no certainty that such will be the case.

As already stated, the estimated freight traffic for the year 1920 will be 410 billion ton-miles, and to haul it will require freight locomotives having an aggregate tractive power of 1,651,228,000 lb. On the basis given above, 153,245,000 lb. additional tractive effort would be needed to bring the aggregate for 1919 up to the proper point, and to this amount must be added 32,218,000 lb. necessary to provide for the increase in freight traffic in 1920. The increase in freight traffic to 418 billion ton-miles in 1921 will require an increase of 32,219,000 lb. tractive power, and the increase to 427 billion ton-miles in 1922 an additional 36,246,000 lb. Normal and deferred retirements of freight locomotives during the next three years make it necessary to provide 190,472,000 lb., and the proportional increase in unclassified locomotives an additional 8,091,000 lb., so that it will require an aggregate increase of 452,490,000 lb. tractive power in freight locomotives in three years. This makes a total to be built of 7,542 units of 60,000 lb. average tractive effort. As heavy freight locomotives cost approximately \$82,000 in

1918, and it is quite probable that this price will continue, the total cost of freight locomotives required in the next three years will be \$618,444,000. This is a yearly average of 2,514 freight locomotives, costing \$206,444,000.

PASSENGER LOCOMOTIVES

The passenger traffic of the railroads of the United States during the decade ending with the year 1914 increased 11,458,246,073 passenger-miles, or 48 per cent. During this same period the number of passenger locomotives increased only 25.8 per cent, but as in the case of freight locomotives the average tractive power increased rapidly.

The passenger locomotives in service in the year 1914 were 23 per cent of the total number of locomotives and the aggregate tractive effort amounted to 396,051,000 lb., or 20.5 per cent of the total for all classes. No figures being available as to the actual aggregate tractive effort engaged in passenger traffic in recent years, it may reasonably be assumed that the same ratio that existed in 1914 (20.5 per cent) will apply. On that basis the passenger traffic for the year 1919 would have required 521,669,000 lb. tractive power, but the total available power was only 473,199,000 lb.

The total available tractive effort on December 31, 1918, being 2,196,648,349 lb., and assuming that 20.5 per cent of this amount was engaged in passenger traffic, this additional tractive effort required for passenger service to bring the total for the year 1919 up to normal would be 48,470,000 lb., and with the increase computed on the basis of 20.5 per cent, 11,404,000 lb. are required for 1920, 10,401,000 lb. for 1921 and 11,702,000 lb. for 1922. To replace the normal and deferred retirements of obsolete passenger locomotives 59,613,000 lb. are required, making a total increase of 141,601,000 lb. tractive power required to be built for passenger service in the next three years.

This would require a total of 3,218 units of 44,000 lb. tractive power each, and as the probable cost of passenger locomotives will approximate \$60,000 each, it will necessitate a total expenditure of \$193,080,000 for this purpose during the next three years.

SWITCHING LOCOMOTIVES

The I. C. C. statistics show that 15.6 per cent of the total number of locomotives in service were switching locomotives, and on the basis of 14 per cent of the aggregate tractive power there were 323,160,000 lb. of tractive power in switching service in the year 1919. Additional power of 33,785,000 lb. tractive effort are required to bring the switching service to its proper proportions, and this amount should be constructed in the year 1920. To meet the normal increase in traffic in 1920 will require 7,105,000 lb., the increase in 1921 will require 7,203,000 lb. and in 1922 it will require 7,891,000 lb. additional tractive power.

Besides these increases, the deferred and regular retirements of switching locomotives to be replaced with modern power will require 40,712,000 lb., making necessary a total increase of 96,696,000 lb. tractive effort in the next three years. Taking 40,000 lb. tractive power as an average for this class of locomotives, this would require 2,417 units, and at an average cost of \$40,000 each the total cost of switching locomotives to be built in the next three years would be \$96,680,000, or a yearly average of 806 locomotives, at a cost of \$32,226,666, which represents the requirements of this class of the service.

SUMMARY

The total increase in the aggregate motive power required in the next three years and the estimated cost is as follows:

Normal increase in lb. tractive power:	
Freight locomotives	261,928,000
Unclassified locomotives	8,099,000
Passenger locomotives	81,988,000
Switching locomotives	55,985,000
Total	408,000,000

Deferred and normal retirements in lb. tractive power:			
Freight locomotives	190,472,000		
Passenger locomotives	59,613,000		
Switching locomotives	40,712,000		
Total	290,797,000		
Cost of replacing retirements:			
3,175 freight locomotives	\$260,350,000		
1,332 passenger locomotives	79,920,000		
1,017 switching locomotives	40,680,000		
Total	\$380,950,000		
Cost of retirements when built:			
9,320 freight and unclassified locomotives	\$142,400,000		
2,760 passenger locomotives	41,700,000		
1,920 switching locomotives	21,300,000		
Total	\$205,400,000		
	Tractive power, lb.	Number of locomotives	Cost
Normal increase and retirements	407,999,600	7,653	\$527,254,000
Deferred retirements	290,797,000	5,524	380,950,000
Total	698,796,600	13,177	\$908,204,000
Average per year for three years	232,599,000	4,392	302,735,000

The cost of locomotives to be retired is taken as equal to the cost in the year 1905, when freight locomotives cost \$15,-250, passenger locomotives \$15,100 and switching locomotives \$11,100. This will retire from service locomotives costing \$205,400,000 when built, and the capital expenditures of the railroads for locomotives will therefore be \$702,804,000 in the next three years, as shown below:

Total cost of locomotives to be built in three years	\$908,204,000
Total cost of locomotives to be retired in three years	205,400,000
Addition to capital expenditures	\$702,804,000

The total number of locomotives that should be built in the next three years is 13,177 and the total to be retired is 12,000 locomotives, making an increase of 1,177.

SHOP AND ENGINEHOUSE EQUIPMENT

In attempting to make an estimate as to the amount that railway repair shops are behind in their shop and engine-house equipment, it will be necessary to know how much has been spent for this purpose in the past few years.

TABLE I—STATISTICS FOR CLASS I CARRIERS

For fiscal year ending	Total operating expenses	Account 302 shop machinery	Per cent of total expenses
June 30, 1911	\$1,844,065,958	\$10,061,423	.546
June 30, 1912	1,898,662,465	10,417,543	.548
June 30, 1913	2,108,947,614	12,182,668	.578
June 30, 1914	2,139,755,988	11,674,904	.546
June 30, 1915	2,021,160,614	8,916,891	.441
June 30, 1916	2,210,892,786	10,295,918	.466
December 31, 1916	2,357,398,412	11,517,657	.489
December 31, 1917	2,829,325,123	14,552,997	.514
December 31, 1918	3,948,132,200	27,520,000	.696
December 31, 1919	4,335,000,000*	30,250,000	.698

* Estimate based on statistics for the first ten months of 1919.

Reference to Table I shows that in the fiscal year ending June 30, 1911, \$10,661,423 was spent for shop equipment and to repair and replace worn-out shop machinery. There was an increase to \$12,182,668 in the following two years, but for the succeeding four years the shop machinery charge was below normal. It was not only small, but a relatively small proportion of the total operating expense. This failure to keep repair shop facilities up to the necessary standard was due, as previously stated, to the difficulty of securing capital, scarcity of labor and the high prices and scarcity of materials. With the beginning of government control in 1918 capital was available, and the priority given to government orders made possible the purchase of railway equipment. Consequently the shop machinery charge practically doubled during the year 1918, as indicated on the chart. This does not mean, however, that twice as much machinery and equipment was repaired and replaced in 1918 as in former years. The fact is that twice as much money was paid for the usual amount of equipment. A canvass of machine tool builders and other manufacturers indicates that 100 per cent is a conservative estimate of the increase in cost of machine tools and shop supplies since 1916.

The ratio of shop machinery to total operating expense in 1911 was .546 per cent. This ratio increased to .578 per cent in 1913 and then, due to causes before stated, dropped below normal for the succeeding four and a half years. During 1918 and 1919 the ratio increased to .696 and .698 per cent, respectively.

If, however, the ratio is considered constant at .578 per cent during this period, a conservative estimate of the deficiency in shop machinery during this period will be obtained. The difference between .578 and the actual ratio for any one year multiplied by the total operating expense for the corresponding year will give the difference between the amount of money that should have been spent on shop machinery for that year and the amount that was actually spent. These amounts have been calculated, and their sums are

TABLE II—1918 STATISTICS OF SIX REPRESENTATIVE ROADS

Name of road	Total operating expenses	Account 302 shop machinery	Per cent of total expenses
Atchison, Topeka & Santa Fe	\$144,912,375	\$884,374	.610
Chicago, Burlington & Quincy	112,067,616	997,507	.890
Southern Pacific	113,652,897	738,237	.650
Chicago, Milwaukee & St. Paul	122,196,105	531,558	.434
Pennsylvania (Lines East)	333,624,523	2,886,760	.865
Pennsylvania (Lines West)	86,559,256	632,213	.729
Total	\$913,003,772	\$6,670,649	4.178
Average per cent			.696

shown in Estimate (a) as \$9,835,000. However, the statistics given in Table I apply to Class I roads only. The operating expenses of Class I roads are about 96 per cent of the total operating expenses of all carriers, and 4 per cent has been added to \$9,835,000, making a total of \$10,229,000. But this equipment and machinery should have been bought previous to 1917, and it will now cost 100 per cent more to replace it, which brings the deficiency up to \$20,458,000.

During the years 1918 and 1919 the amount of money spent for shop machinery was greater than the average, but the machinery and equipment actually acquired was probably less than normal, due to the depreciated value of the dollar. The amount of money spent during the same period for additions and betterments to take care of increased business was wholly insufficient. The replacement value of railway shop machinery in the United States is \$292,200,000. Inasmuch as the annual increase in equipment has been not less than 3.70 per cent and it will require at least 4.2 per cent increase in shop facilities to handle this equipment, the necessary additions and betterments may be expressed as .042x2x292,200,000=\$24,450,000. The total deficiency in shop machinery and equipment up to the present time, therefore, is shown in Estimate (a) as \$44,908,000.

Data extending over a four-year period show that only 67 per cent of the shop machinery charge represents material, the balance representing the labor required to repair and replace the worn equipment. Consequently, as shown in Estimate (b), there is \$20,250,000 worth of material in the annual shop machinery charge. This must be increased by 4 per cent to include all roads; and in a period of three years the total estimated amount of material to be bought will cost \$64,470,000.

That this figure is not excessive may be shown by a consideration of reasonable depreciation charges for the three-year period. It is true that some shop machinery has been used for 20 years or more, but with the continual modern changes and improvements it is doubtful if any machine will have a useful and efficient life greater than 15 years. This means an annual depreciation of 6.67 per cent, which for three years on an investment of \$292,200,000 is \$58,-500,000. In other words, the estimate of \$64,470,000 for shop facilities would hardly do more than cover shop machinery depreciation.

Additions and betterments, being chargeable to capital

account, provide the necessary equipment to care for increased business. In order to estimate future needs, it is necessary to examine past expenditures for this account. In the 30 months from June 30, 1914, to December 31, 1916, only \$6,063,719 was spent for shop machinery additions and betterments. During the following year \$6,000,000, and in the first year of government control \$7,698,596 were spent for machine additions and betterments, but that this amount was entirely inadequate for the needs is indicated by the fact that only 35.2 per cent of the authorized additions and betterments were actually made.

According to estimates made in 1916, the total value of railway shop machinery in the United States amounted to \$146,100,000. Referring to Estimate (c), the replacement value of this machinery in 1919 would be at least \$292,200,000. Assuming then that the plant must be increased 4.2 per cent per annum to care for the new equipment, the total investment in the next three years must be \$36,780,000.

The total amount of money that should be spent during the next three years for shop equipment and machinery, as shown in Estimate (d), is \$146,158,000. This amount is probably less than the actual needs. The magnitude of the

material costs are for machinery, which means that during the next three years \$54,100,000 should be spent for railway shop machinery and machine tools.

The summary given above is exclusive of the structures required for shops and terminals. According to the estimate of the Railway Age, \$250,000,000 should be spent on these buildings during the next three years.

THE INCENTIVE FOR HIGHER EFFICIENCY*

BY D. C. BUELL

Director, Railway Educational Bureau, Omaha, Neb.

Our ablest statesmen, economists, and financiers, as well as our leading business men are confronted with an industrial problem—perhaps the most serious in the history of our country—the labor unrest which is almost universal. My experience with a small organization of railroad men in France taught me some lessons about this problem. These men in a strange environment, with almost no facilities for efficient work, housed in barracks, eating in the open from their mess kits, performed one of the quickest and most efficient jobs of erection work that I have ever witnessed. The reason for this efficiency was that there was an incentive which caused them to put forth their best efforts to accomplish the task in hand.

Our labor unrest today is largely due to lack of incentive. We do not see the future clearly. You men are in intimate daily contact with a large proportion of the workers employed in the various shop crafts on our American railroads. You must be the leaders in an educational movement that will prove to those with whom you come in contact that there exists today one of the greatest incentives for doing efficient work that has ever appealed to the railroad men of this or any other country. That incentive is nothing less than the re-establishing of permanent prosperity for the American people. We must all become teachers of economics. The lesson to be taught is that high wages and permanent work depend on production. We must give a fair day's work for a fair day's pay. We must bend every effort toward wiping out the thought that the curtailment of production means more jobs and better living conditions.

The present standard of wages can be and will be maintained if they are earned. They cannot be and will not be maintained if production is decreased in proportion as wages are increased. We Americans receive the best wages for the shortest hours of work that are received by any workmen in the world. In order to maintain and improve this standard we must give full value for what we receive. Getting something for nothing is contrary to the laws of nature. Production is the basis of the solution of our present day problems. Profiteering can and will be wiped out by existing law or by new laws formulated to meet the new conditions. Labor itself has the power to resist unfair practices. Capital and labor are partners. They must co-operate. A spirit of loyalty must be obtained not only between the workman and his boss, but between the boss and his workmen.

Those 200 railroad men in France were a host in themselves. They overcame difficulties that were seemingly insurmountable. They did their work cheerfully, willingly and happily. It was a pleasure to them and their production was phenomenal. If the vast group of railroad workers in America today felt that same spirit of co-operation, that same spirit of comradeship, that incentive to accomplish things because of the spirit of loyalty pervading the work, production would increase, the cost of living would decrease, the present standard of wages would be maintained or bettered and there would be a joy in work that would make for continued peace of mind and prosperity.

*From an address at the General Foremen's Convention.

ESTIMATE

(a) Deficiency in shop machinery:			
From June 30, 1913 to December 31, 1917—

Value of shop machinery in 1916.....	\$146,100,000		
Replacement value in 1920.....	292,200,000		
Annual equipment increase of 3.7 per cent will require 4.2 per cent investment in machinery	12,260,000		
For three years.....	3		
Total	\$36,780,000	\$36,780,000	
(d) Grand total (a) + (b) + (c).....		\$146,158,000	

result gives some indication of how serious the situation has become. The cost of all materials has practically doubled in the past three years, shop employees' hours have been reduced to eight hours and wages have increased on the average at least 100 per cent. To offset these increased costs and place back into service the locomotives now held waiting repairs, it will be necessary to make up previous deficiencies in equipment and modernize all shops.

Automatic and semi-automatic machinery, for example, should be more generally used in back shops where material is manufactured for the whole system. Another field that deserves particular attention is the enginehouse machine shop.

The material and equipment purchased for railway shops and included in this discussion is of almost infinite variety from belts, air hose, rope and packing to boilers, cranes, welding equipment, lathes, etc. The largest single item is machinery and tools. Approximately 38 per cent of the total

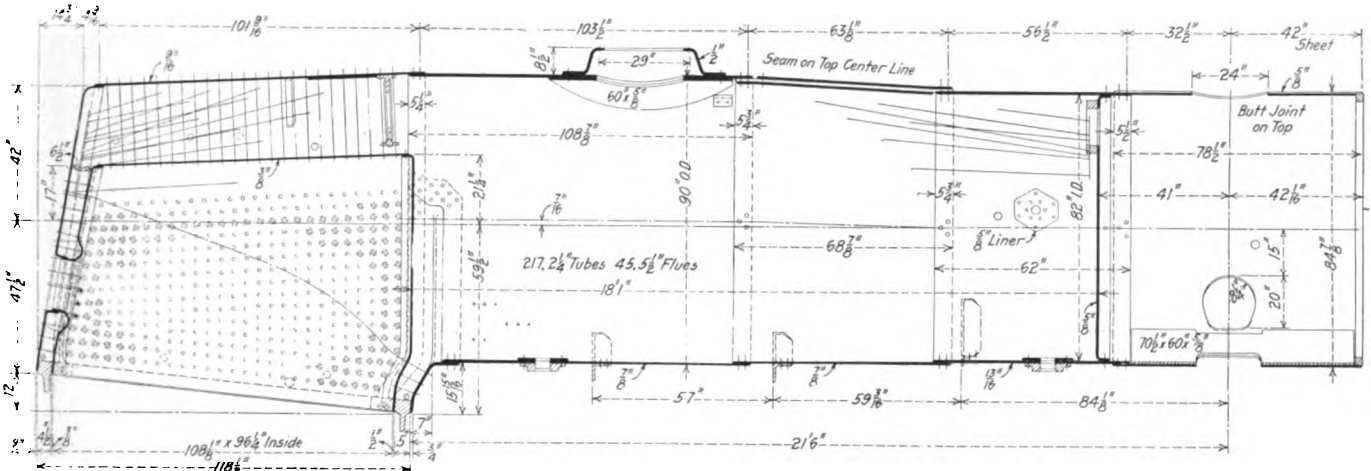

Elevations and Sections of the Ten-Wheel Switcher Built by the American Locomotive Company for the Chesapeake & Ohio

is on the outside, in line with the main rod. The guides and crosshead shoe being solid bronze with very liberal bearing surfaces, designed to give long wear.

The total length of this locomotive from the front bumper to the tender end sill is 75 ft. 9 1/4 in., the overall height is 14 ft. 11 3/4 in. and the width over running boards 10 ft. 5 in. The locomotive frames are 6 in. wide and have ample depth over the pedestals to provide the required strength to

box, with a double row of 1-in. rivets, 5 3/4-in. at the two intermediate seams, with double rows of 1 1/4-in. rivets and 5 1/4-in. at the firebox with a double row of 1 1/8-in. rivets. The boiler is equipped with a Schmidt superheater, having a heating surface of 945 sq. ft. The firebox is 108 1/8-in. long by 96 1/4 in. wide inside, has an average height of 72 5/8-in. and a grate area of 72.2 sq. ft.

The tender tank is built unusually low and long and the

Extended Wagon Top Boiler for the Chesapeake & Ohio Ten-Wheel Switching Locomotive

support the heavy weight of the locomotive. The journals of the main driving axles are 11 1/2 in. by 23 in. and the other four axles have journals 10 1/2 in. by 14 in.

The cab fittings are arranged on the backhead in the most convenient location for the engineman and particular care

side plates of the coal space are set in to permit an unobstructed view toward the rear. The tank is 32 ft. long by 10 ft. wide, by 5 ft. high inside, and has a water capacity of 15,000 gallons. The coal space has a capacity of 15 tons. The tender frame is of cast steel, having side sills 10 in.

Cross Sections of Boiler for the Chesapeake & Ohio Heavy Switcher

has been taken to afford an unobstructed view in both directions from the cab.

The boiler is of the extended wagon top type with a wide firebox. It has an inside diameter of 88 1/4 in. at the dome course. The longitudinal seams are on the top center line, have inside and outside welt strips and are strongly riveted. The circumferential seams are lapped 5 1/2 in. at the smoke-

deep and intermediate sills 13 in. deep. The vertical webs of these sills are 1-in. thick and are very strongly ribbed and webbed, making a most rigid frame that will withstand any stress that may be put upon it in heavy switching service.

The tender trucks are of the same design as those used under the tenders for the Chesapeake & Ohio Mallet type locomotives. The truck side frames are 6 in. wide and are

of cast steel. The bolsters are also of cast steel and are supported by triple elliptic steel springs. The wheel base is 5 ft. 10 in., and the wheels 33 in. in diameter and the journals 6 in. by 11 in.

The specialties include the Cole long main driving boxes, Watters pneumatic sanders, Nathan lubricators and non-lifting injectors, Hancock combined stop and check valves and hose strainers, "Loco" incandescent headlight equipment,

February, 1919, has been very satisfactory. They have not only handled the heavy trains easily but have proved to be as well adapted to a lighter switching service as the medium sized locomotives.

Back Section Rod Outside of Side Rods and in Line with Main Rod

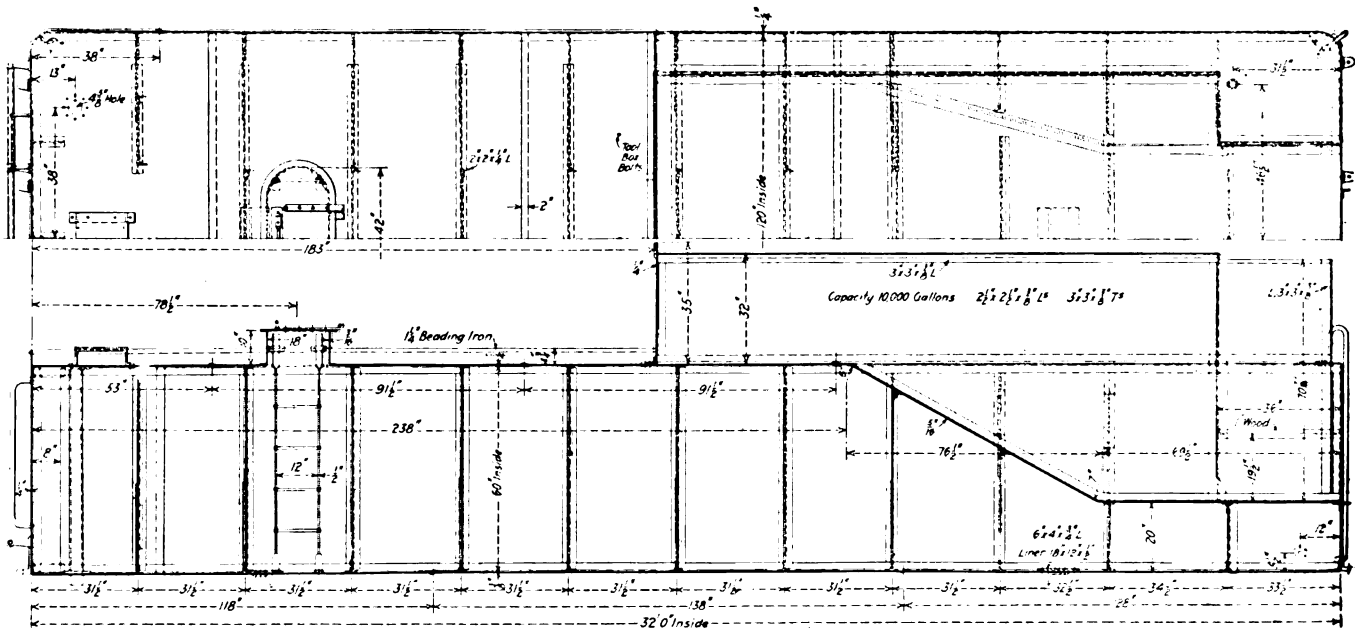

Half Front and Rear Elevations of Tender for C. & O. Ten-Wheel Switcher

Consolidated safety valves, Franklin pneumatic grate shakers, Lewis power reverse gear, Economy radial buffer, Farlow-Westinghouse draft gear, Sharon tender and pilot couplers, Commonwealth cast steel pilot beam and tender frame, Hunt-Spiller gun iron cylinder and valve packing rings and steam chest bushings, Cambria Coffin process axles, Schmidt superheater and Westinghouse-American brakes with two 9 1/2-in. pumps. The piston rods and crank pins,

ROLLING STOCK ORDERED AND BUILT IN 1919

New Low Records in Locomotive and Car Orders Production of Freight Cars Greater than in 1918

THE number of locomotives ordered for service in the United States during 1919, according to the statistics of the Railway Age, were only 214. This marks a new low record in the history of the railroads of the country. The orders placed by Canadian roads either with American or Canadian builders totaled 58, while orders for export reached a total of 898, a total of all three of but 1,170. In other words, the foreign orders and the domestic together were barely sufficient to bring the total up to the domestic orders alone of the poorest year since 1901, namely, 1908, when only 1,182 locomotives were ordered for domestic service.

TABLE I—THE LOCOMOTIVE ORDERS OF 1919

For service in the United States.....	214
For service in Canada.....	58
For export to other countries.....	898
Total.....	1,170

The 1919 totals quoted above compare with figures for 1918 of 2,593 for domestic service in the United States, 209 for Canadian roads and 2,086 for the American forces in France or for export. The total of locomotives ordered for domestic service represents only those locomotives ordered by lumber roads and industrial lines; there are but few orders for railroad service.

TABLE II—ORDERS FOR LOCOMOTIVES SINCE 1901

Domestic orders only			
Year	Loco- motives	Year	Loco- motives
1901.....	4,340	1908.....	1,182

1917.....	2,704	3,438	6,142
1918.....	2,802	2,086	4,888

The number of locomotives built in the United States and Canada in 1919, according to the compilations of the Railway Age, was 3,272, of which 2,162 were built for domestic use and 1,110 for export. Of the domestic total 2,055 engines are shown as having been built in the United States for use on the railroads in this country and 107 in Canada for use in that country. The totals given are but one-half

those of 1918, when 6,475 locomotives were produced in the United States and Canada. It will be noted, however, that

FREIGHT CARS ORDERED AND BUILT

the total domestic output of 1919 was considerably above that of the years immediately preceding 1918.

The number of freight cars ordered for domestic service in the United States in 1919 totaled only 29,893, marking a figure so low as to make almost ridiculous a comparison with the domestic orders of previous years. There were ordered for service in Canada 3,837 freight cars and for export to other countries 3,994. These totals compared with domestic orders placed in 1918 for cars to be used in

TABLE IV—THE FREIGHT CAR ORDERS OF 1919

For service in the United States*.....	22,062
For service in Canada.....	3,837
For export to other countries.....	3,994
Total.....	29,893

*Including 15,295 tank cars.

the United States of 114,113; for roads in Canada, 9,657, and for the A. E. F. and for export to other countries, 53,547.

The exceptionally small domestic total in 1919 resulted from the fact that the United States Railroad Administration has placed no orders for cars in 1919 and that the railroads have ordered but a very few. In fact, the larger part of the orders that have been reported have been placed by private car lines, over two-thirds of the orders being for tank cars.

The orders for export, totaling in the neighborhood of but 4,000, were considerably below the totals of 1917 and 1918. They were less than one-fourth as great as those for 1915, the year in which the war demands began to make themselves effective. They were less than one-twelfth as great as in 1918. The domestic, Canadian and foreign orders combined

TABLE V—ORDERS FOR FREIGHT CARS SINCE 1901

Domestic orders		Domestic and foreign	
Year	Freight cars	Domestic	Foreign
1901	193,439	199,792	18,222

Year	United States			Canadian			Grand total
	Domestic	Foreign	Total	Domestic	Foreign	Total	
1913	176,049	9,618	185,667	22,017	22,017	207,684
1914	97,626	462	98,088	6,453	6,453	104,451
1915	58,226	11,916	70,142	1,758	2,212	3,970	74,112
1916	111,516	17,905	129,421	5,580	135,001
1917	115,705	23,938	139,643	3,658	8,100	11,758	151,401
1918	67,063	40,981	108,044	14,704	1,960	16,664	124,708

represents by no means as large a share of the productive capacity of the country as might be wished. It is, however, considerably in excess of the output of the car-building plants of the United States of 108,044 (124,708 including Canada) in 1918, or of 139,643 (151,401 including Canada) in 1917. In fact, it has been exceeded but twice since the big total of 284,188 (including Canada) in 1907, namely, in 1910, when there were produced in the United States and Canada 180,915 cars, and in 1913, when 207,684 were produced.

The unfortunate feature in the comparatively large output figures of 1919 is the small number for domestic use. While the total output is large, it will be noted that that for domestic use alone, while it is above the level of 1918, when 67,063 cars were produced for use in the United States, is not up to the totals of 1916 or 1917 even, in which years the output of freight cars was not sufficient to keep up with the increasing demands of the business offered for railway transportation.

FEW PASSENGER CARS BUILT IN 1919

The figures showing the new orders and the production of passenger cars in 1919 indicate that that industry has as yet by no means recovered from the practical cessation of business resulting from the war and its attending circumstances. The number of passenger cars ordered

TABLE VII. THE PASSENGER CAR ORDERS OF 1919

Total	782

in 1919 totaled 782, of which 292 were for service in the United States, 347 for Canada and 143 for export. Owing to the fact that there have been a number of passenger car orders placed within the last few weeks these numbers are considerably in excess of those of 1918, when 131 cars were

1917
1918
1919

ordered for domestic service and 26 for export, but, of course, they are not at all up to the totals for 1917.

The production of passenger cars in the car building plants of the United States in 1919 (excluding Canada), totaling 466, of which 306 were for domestic use and 85 for export, is likewise far below the output for 1918, when 1,573 cars were built, including 1,481 cars for domestic use and 92 for export. The output of passenger cars in 1919 was the lowest since the compilation of these figures was begun.

The orders on hand for passenger cars at present promise a somewhat larger year from the production standpoint in 1920 than in 1919.

DEVELOPMENTS IN THE SHOP LABOR SITUATION

Summary of Reports Showing Changes in Wages and Hours of Various Classes of Employees since 1917

THE United States Railroad Administration has prepared very complete reports of the number of employees, rates of pay and the average of compensation in December, 1917, and each month from January to July, 1919, at the request of the Senate. This information was submitted to the president of the Senate by Director General Hines, and a summary of the data relating to the shop crafts is shown in the tables below.

There has been a widespread belief that there was a con-

Considering only the shop crafts, the average increase in the number of employees has been 19.2 per cent. The change in the average number of hours worked per employee varies greatly for the different classes. The general foremen were the only class showing an increase, the average number of days worked in July, 1919, being 29.9 per cent as compared with 27.1 per cent in December, 1917. On the other hand, the average number of hours worked by hostlers during July, 1919, was 97 hours less than in December, 1917, and by

Total	409,527	488,454	78,927			

This report is compiled according to the classification prescribed by the Interstate Commerce Commission in accordance with the Act to regulate commerce, which classification has been the prescribed form since July 1, 1915.

The classification of employees prescribed by the Interstate Commerce Commission and used in the reports, does not correspond with the classification of employees used in the wage orders of the Railroad Administration, with the result that employees in a given class (of wage orders) receiving either higher or lower wages may be included with the employees of another class (of the Interstate Commerce Commission classification).

A comparison of the number of employees in January, 1919, and December, 1917, is misleading, because in December, 1917, on account of the extreme cold weather, much outside work had of necessity to be suspended. In addition, there was a scarcity of labor, in consequence of the competition of war industries, and the generally higher wages paid by them which had attracted many employees from railroads.

On the contrary, the weather was exceptionally mild in January, 1919, and permitted the prosecution of an unusual amount of outdoor work; moreover, the labor supply was relatively greater because of higher wages, and in consequence of the cessation of war activities. In addition, the Railroad Administration had not yet been able fully to reduce its forces from what had been necessary to handle the peak load which was reached about the time of the signing of the armistice a couple of months earlier.

In considering the number of employees in view of the changes in the working conditions between 1917 and 1919, the number of hours worked should be carefully noted.

considerable increase in the number of railway employees and the total number of hours worked. The report shows, however, that while more employees are now used for a similar amount of work, the increase has resulted largely from the effect of the introduction of the eight-hour day in reducing

car inspectors 89 hours less. The average increase in the unit compensation for all classes of employees was 53 per cent. The increases for shop crafts in most cases were considerably greater. Taking into account the increase granted in September, 1919, the rate of pay for car inspectors in-

Note—Italic figures indicate estimate of increase to shopmen in September, 1919, retroactive to May 1, 1919.

the number of hours worked by each employee. Considering all classes of employees, the number employed by the railroads under government control increased from December, 1917, to July, 1919, by 11.2 per cent, as shown in the following table. During this same period the number of hours worked decreased 3.9 per cent and the total compensation increased 36 per cent.

creased 117 per cent. The only classes of employees in the mechanical department receiving less than the average percentage of increase were the machinists, boilermakers and blacksmiths. It should be noted in this connection that these crafts are among the highest paid classes of railroad employees, and although they have not received increases proportionate to the other crafts this is quite consistent with the

original policy of the wage board, which recommended increases on a graduated scale.

It should be noted, also, that a comparison between the rates of pay in 1919 with the single month of December, 1917, is likely to be misleading, because some classes of employees had prior to December, 1917, obtained reductions in hours which resulted in their average compensation per

per cent, taking into consideration the shopmen's increase. The wages in December, 1917, were, however, on a higher basis than the average for that year, because of the large number of increases made by the railroads during the last year of private management, and the increase for July, 1919, over the average for 1917 was given by Mr. Hines as 45.3 per cent.

REPORT ON COST OF LIVING DOES NOT JUSTIFY WAGE INCREASE.

Executive officers of the railroad shop crafts affiliated with the Railroad Employees' Department of the American Federation of Labor called on Director General Hines on December 20, just before the Cummins bill was passed by the Senate, to discuss, according to a statement issued by the Railroad Administration, "the question of the cost of living," which is taken to mean that they renewed their request for a general increase in wages which has been held in abeyance since August, when the President and Mr. Hines asked them to wait a reasonable time to allow the government an opportunity to try to reduce the cost of living. According

	Number of employees	Increase in percentages as compared with December, 1917
1917—December	1,703,748	...
1919—January	1,848,774	8.5

approximately 56 per cent by including the shopmen's increase, but that because of the reduction in hours the average increase in monthly compensation was 32.9 per cent or 35.3

to the official announcement, Mr. Hines explained that he hoped to be able in a few days to give more definite advice on this subject, and it was agreed that a further conference would be held a few days later.

On December 22 Attorney General Palmer issued a statement in the way of a report to the public on the results of the government's campaign against the high cost of living, in which he announced that since August it had been held in check, whereas statistics had usually shown a rise in prices during the fall months and that a drop may be expected between January 1 and March 1. The report, which was authorized by a committee of government officials that have taken part in the campaign, including Mr. Hines, is understood to form the basis of the government's answer to any further wage demands.

The demands of the shop employees were originally presented in January and were based on an increase for skilled mechanics from 68 to 85 cents an hour. Increases ranging from 4 to 9 cents an hour were granted them in August by way of readjustment at the time. It was announced the government could not then consider further increases to meet the cost of living, because they would tend to increase it still further. Most of the other organizations of railway employees also presented demands, which have also been held in abeyance. What position they will take in view of the report that the cost of living statistics do not justify further increases has not yet been disclosed. It was stated that no definite date had yet been set for the conference with the shopmen, but B. M. Jewell, head of their committee, was quoted as saying they had no intention of striking.

THE INSPECTION OF FREIGHT EQUIPMENT

First of a Series of Articles Describing the System
of Handling Inspection Used on the C. M. & St. P.

BY L. K. SILLCOX

Master Car Builder, Chicago, Milwaukee & St. Paul

THESE instructions, effective date of issue, supersede all previous or heretofore existing regulations, and shall not be modified or revised, except by authority of the undersigned.

Car foremen will be held individually responsible for the enforcement of these instructions, and are to notify the master car builder in case any condition arises wherein they find it impractical or impossible to maintain the regulations as set forth.

GENERAL.

The data which follows has been worked up through the co-operation of the transportation department, the operating department and all concerned, having one purpose in mind; namely, the safe and prompt movement of freight equipment. The conclusions reached as set forth are the results of years of experience and the best judgment of the combined effort of those interested on the railroad. It is, therefore, necessary and obligatory that these instructions shall be lived up to literally, and no excuse whatever will be accepted for disregard of them. Good judgment is necessary in putting these regulations into practice.

Knowing that certain things must be done, and issuing instructions to do them, does not always mean they will be carried out or that the instructions issued will be complied with. Something more is required. The men in charge must be capable not only of issuing instructions, but capable of knowing whether these instructions are being complied with or not, and they should also be capable of turning the interpretation over to their assistants in workable form and selecting men who are capable of complying with these regulations.

If this statement is true, then we should have thorough capable and efficient foremen in charge of all stations who know when a car is inspected and how to inspect it as well. They should know when a car is properly repaired and how to repair it. If they are capable of doing this they should then be capable of selecting the right man to see that this work is properly performed, and so on right down to the point of seeing positively that neglect and inefficiency are never allowed to creep into the service.

Inspectors should be given trains to handle, as outlined on the charts on page 21, and they must be permitted to hold them a sufficient length of time to give each car the needed inspection and repairs or to shop defective cars out for repairs. After an inspector has shopped a car for defects which make it unsafe to be continued in service, no

one should be permitted to cause such a car to be placed back in service until the repairs for which the car was shopped have been properly made, or improper repairs corrected. One giving or assuming such authority would by his act destroy the effort made toward obtaining safe movement and would be a promoter of ill results. It should be considered just as serious and dangerous for one to remove a bad-order card from a defective car and permit it to go into service without necessary repairs being made, or permit a car to go into service with a bad-order card on it without the repairs being made, as it would be for one to change a signal in front of an approaching train operating under the automatic block system.

Cars once inspected and passed as being fit for service should be in such condition that when inspected again at the next inspection point they will not be shopped out for defects that existed at the time of previous inspection, neither should they fail while in movement due to such defects; in other words, should an inspector pass a car as being safe and fit for loading at Chicago, that car should be in condition to continue through to Tacoma or any other destination without being shopped out or breaking down in movement, due to defects existing when the car was inspected at Chicago. When a car is repaired on the shop tracks at Minneapolis for movement to Omaha for loading, it should not be necessary to shop it for defects that existed when it was placed on the shop tracks, or for improper repairs made at Minneapolis, on or before its arrival at Omaha. No car should be placed for loading until first inspected and given needed repairs. Unless we are able to obtain these desirable conditions, our inspection or our repairs are not uniform, or our supervisors are not capable or efficient, or some one is removing bad-order cards or causing cars to leave inspection or repair yards before they are in proper condition for service.

Such practices, if they do exist, must be corrected or we cannot expect to establish the results which are required for safe and economical operation. Uniform inspection and repairs mean less loss of life and limb of passengers and trainmen, greater car mileage, fewer accidents, less destruction of equipment and property, less repeated shopping of cars, greater car supply, less need for the purchase of new equipment, decreases in the cost of operation and maintenance, prompt handling of business, greater satisfaction to shippers, better earnings for railroads and a more satisfactory dividend for stockholders.

of faulty construction or decay or age, are liable to be blown off and fall on the track and cause an accident.

10. Q—Have you any detailed instructions relative to the way the different character of lading should be placed on cars and secured to insure its safe movement over railroads?

Answer—Yes. The latest revised "Rules Governing the Loading of Stone, etc., Loading and Carrying of Structural Materials, Plates, Rails, Girders, etc.," as prescribed by the Master Car Builders' Association.

11. Q—Where it is found that these rules and cuts do not apply to lading being prepared for shipment, what should be done?

Answer—Special instructions must be asked for.

12. Q—Do you understand that railroads are liable to a fine for hauling cars with Safety Appliance Act defects?

Answer—I do.

13. Q—What do the Safety Appliance Act defects consist of?

Answer—Defective couplers and parts that make the couplers inoperative to the extent that they will not couple in impact, or if the coupler is less than 31½ inches or more than 34½ inches from the top of the rail to the center line of the coupler shank, defective uncoupling mechanism, hand or air brakes, hand holds, steps, ladders, running boards or other parts covered, and to be found in the rules for the inspection of safety appliances.

16. Q—Is there any other information concerning air brakes, their operation and maintenance that it is important that inspectors become familiar with?

Answer—Yes. The air brake rules, which treat on the details of this subject, contain important information that each inspector should become familiar with.

17. Q—What piston travel should be maintained on car equipment?

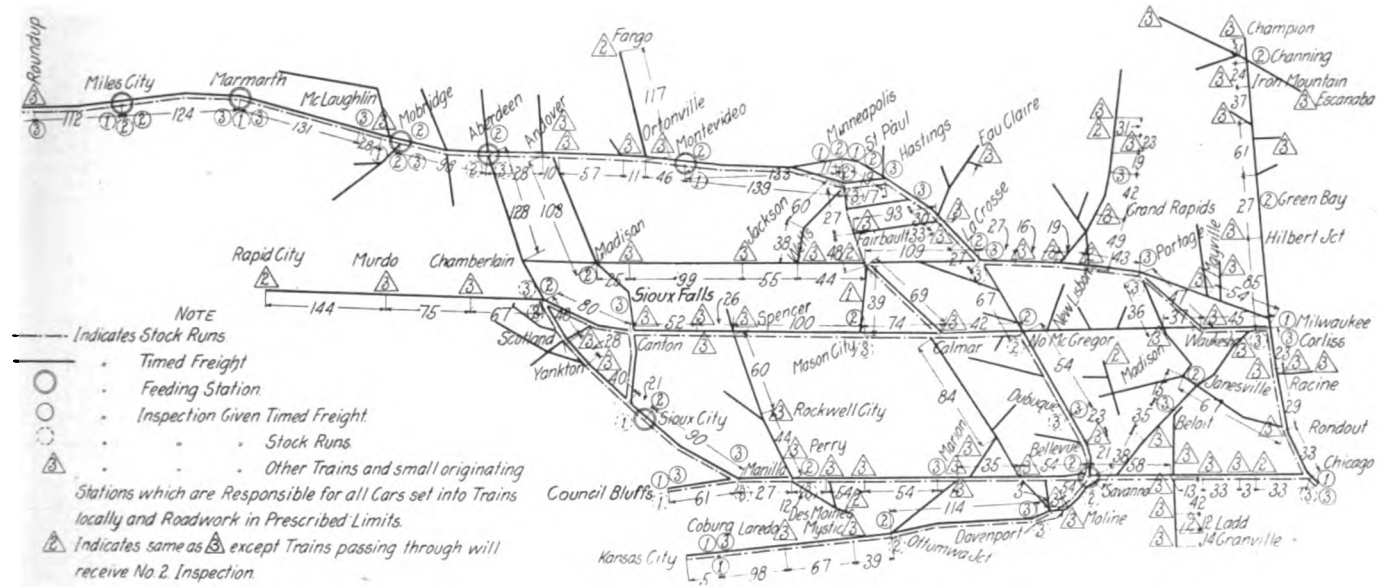

Answer—On cars equipped with automatic slack adjusters it should not be less than 7 in. nor more than 8 in. when the car is standing.* When brakes are applied on cars not equipped with automatic slack adjusters the piston travel must be from 5 in. to 7 in., and in adjusting piston travel it should be 6 in., as per rules and regulations governing air brakes and air signals.

18. Q—What is the underlying idea or principle of the Master Car Builders' Association rules?

Answer—To facilitate the interchange of cars; to establish uniformity of practice in inspecting and repairing them, and in rendering bills for such repairs. Also to make car owners responsible for and chargeable with repairs to their cars necessitated by ordinary wear and tear in fair service.

19. Q—When is a company operating the cars of another company responsible for defects on such cars?

Answer—When the defects are due to unfair usage, derailment or accident, and for improper repairs made by it to

The Lines of the Chicago, Milwaukee & St. Paul, Showing the Through Freight Runs and the Class of Inspection Division Points

14. Q—Why is it essential that journal boxes, journal bearings, axles and lubrication be maintained in good condition?

Answer—To prevent failures of such parts in service and the expense and delay to cars and freight on account of setting out cars on the line for repairs.

15. Q—What attention should inspectors give to air brakes?

Answer—They should see that the air hose, pipes and other parts are maintained in such condition as to keep the brakes in good operative condition; that the brake cylinders, triple valves, high speed reducing valves, slack adjusters, safety valves and dirt collectors are cleaned on all cars, as provided for in the Master Car Builders' Association Code of Rules or other existing instructions.

Supplementary reservoirs on passenger train cars equipped with the LN brake equipment must be cut in when such cars are in passenger trains, but supplementary reservoirs must be cut-out when passenger train cars equipped with the LN equipment are put in freight trains.

such cars; also for certain other improper repairs, which are provided for in the M. C. B. rules.

20. Q—What cars must be accepted in interchange?

Answer—All cars that are in safe and serviceable condition that are free from any safety appliance defect and otherwise meet the requirements of the M. C. B. rules.

21. Q—Who is to be the judge of the safe and serviceable condition of cars offered in interchange?

Answer—The receiving road in all cases not specifically provided for in the M. C. B. rules.

22. Q—Under what condition would you, as delivering inspector, issue an M. C. B. defect card?

Answer—When the company which I represent is responsible for defects according to the M. C. B. rules for which a card is requested.

23. Q—Under what condition would you refuse to issue a defect card?

Answer—If the owner of the car is responsible under the

*This is added as a word of caution when passenger train cars are employed in freight train service.

M. C. B. rules for the defects for which the card is requested to cover.

24. Q—When should a bad-order card be attached to a car?

Answer—In every instance that the car or lading is found to be defective.

CLASS 1 INSPECTION.

Class No. 1 inspection, otherwise known as originating or initial inspection and repairs to equipment coming empty or loaded to our lines, also covering the necessary action on loaded equipment before leaving the initial point of loading.

The greatest responsibility we hold as a department is with respect to seeing that we have as nearly a perfect car for any particular lading or routing over our lines as possible, and also to see that the load is so placed in the car by the consignor that it does not cause damage to the car or

CARS AT ORIGINATING POINTS.

(Referring principally to stations, Chicago, Milwaukee, Omaha, Kansas City, Coburg, Council Bluffs, Minneapolis, St. Paul, South St. Paul, Aberdeen, Mitchell, Sioux City,

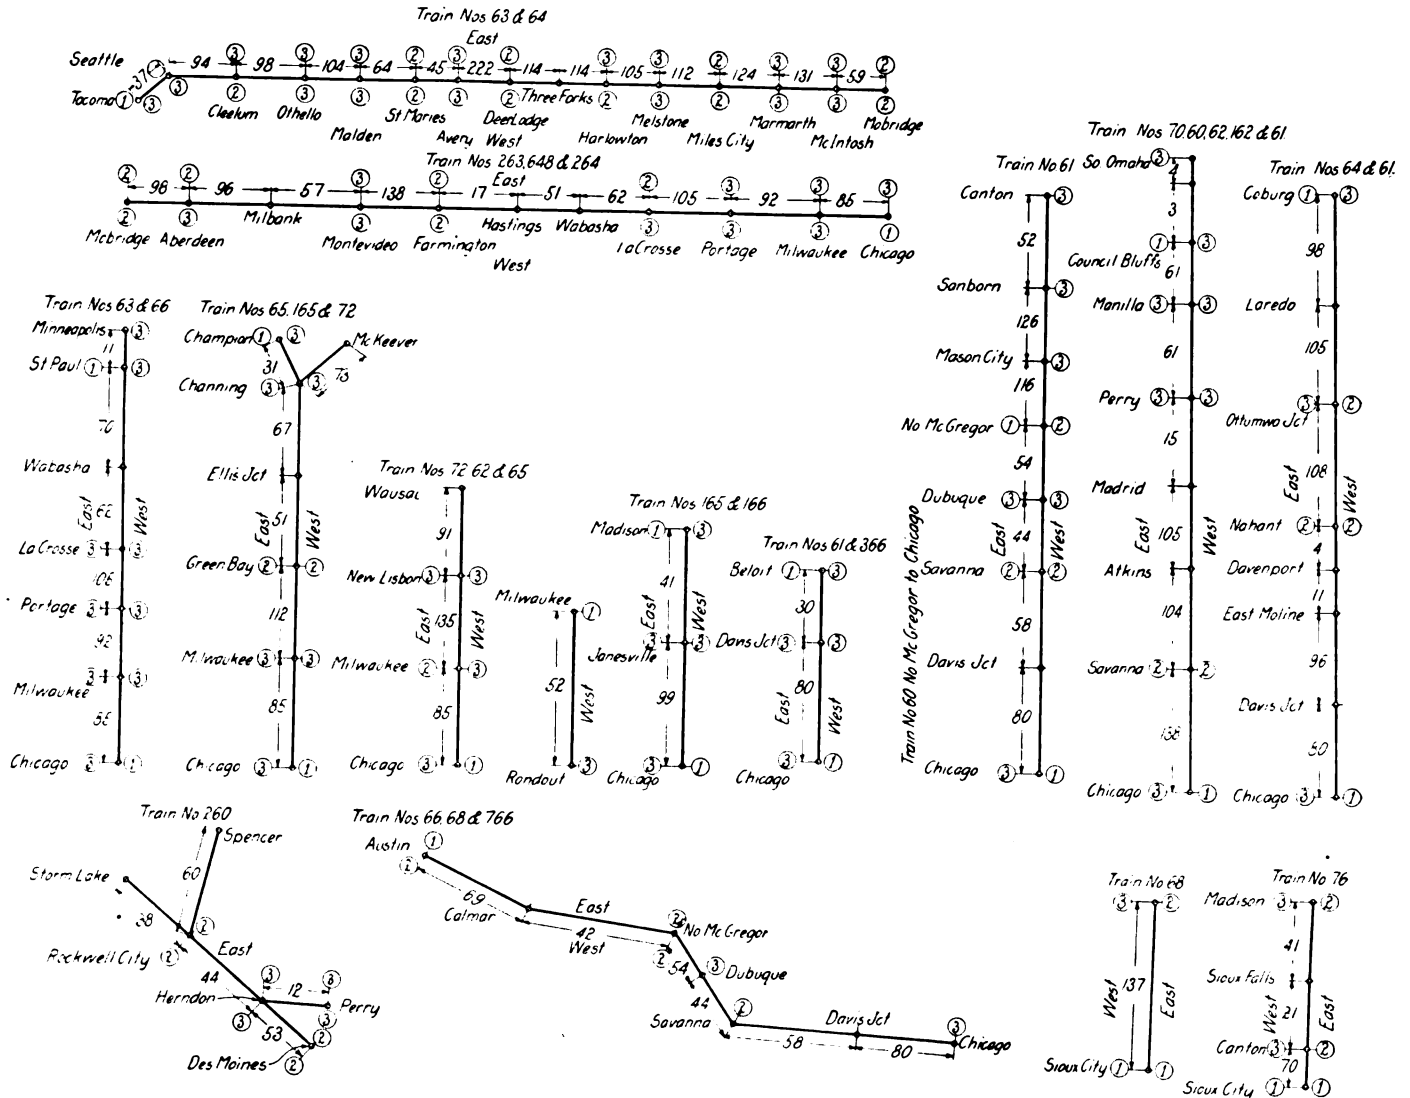

Diagram of Through Freight Trains Showing Provision for Inspection

Rapid City, Mobridge, Spokane, Seattle, Tacoma and all originating stations.)

A daily inspection should be made of every freight car standing in yards, industry tracks or at loading stations at all points on the railroad where carmen are stationed. Where conditions will permit, each inspector should be assigned to a particular part of this work. Defects discovered should be either repaired at once or so marked that they will be readily noted by car repairers or box packers, in cases where car inspectors cannot handle the work due to local conditions. The maximum time trains may be held for Class No. 1 inspection is five hours, less time when possible. Cars are to be set out if the work cannot be completed in this period, provided it is desired to move the train. The following will be some of the work necessary in placing trains in proper condition at No. 1 stations:

itself, thereby co-operating to the extent of having the shipment and equipment reach its destination and the consignee in the condition and time that it should, thus overcoming unnecessary expenditures and complaints from shippers. For this reason there must be the very closest co-operation between all employees of this department and those who are placing the loads in the car, both at freight houses, industrial plants and all other similar loading points, to see that the M. C. B. rules are strictly observed, both in open and closed cars, to protect the lading en route against shifting and otherwise, and also on double and triple loads, to see that they are carefully built up to insure safe movement in line with current M. C. B. loading rules. These rules, as in effect, are revised from year to year and are perfected to cover the interchange of equipment throughout the country.

It is important to remember to give close attention to the

necessity of providing proper doorway protection and blocking on house cars to overcome damage to the lading and injury at the doorway en route.

Granting that all of the previous requirements have been complied with, the car is accepted for train service to its destination and should proceed without serious difficulty. Primarily intermediate inspection is intended for the purpose of a protection on defects occurring through unfair service that impair the strength or serviceability of the car.

There would, naturally, seem to be little use for intermediate inspection, but when taken collectively the division of our railroad centers are so distributed that when the equipment reaches these intermediate terminals it has covered approximately from 150 to 300 miles, and the service demands an examination of the running gear, a re-examina-

taken for switching and advanced to the receiving yard as a rule, where the air brake test, repairing and box packing is covered. The disposition of through business under such arrangements can be based on the interchange of 8,000 loads and 3,000 empties every 24 hours, with an average of one car out of ten as a cripple to the repair track. This indicates why a plea is made for better equipment at the initial point of loading to overcome serious delays that must be faced en route if such action is not taken, and which is kept constantly before us by the transportation department.

CLASS 2 INSPECTION.

Class No. 2 inspection, otherwise termed as that attention given cars passing from one grand division to another or having operated 300 to 500 miles without previously having had either No. 1 or No. 2 inspection.

This class of inspection contemplates suitable attention being given cars at certain definitely assigned divisional points and small originating and interchange stations. Under this classification wheels and axles should be given careful inspection. Brake shoes having a reddish color indicate that there has been a long application of the brakes which heat the wheels, and the latter should be carefully examined for cracks in the plates. Box lids should be opened and the condition of the lubrication and journals ascertained. Any bearing showing an indication of heating should receive the necessary attention.

Draft gear and couplers should be examined for the purpose of detecting defects that may have come into existence. Safety appliances must be repaired when found defective.

Brake beams and connections should be examined to see that they are up and in proper and safe condition. Brakes should be tested by the incoming engine making a 20-lb. reduction from a 70-lb. train line pressure and the brakes left set while the inspection is being made. The condition of truck sides and arch bars should also be observed and all missing nuts replaced and loose nuts tightened up.

Inspectors should so locate themselves in the yard that the train will pass them, when entering their respective yard, with a view of discovering loose and defective wheels and brake gear.

CLASS 3 INSPECTION.

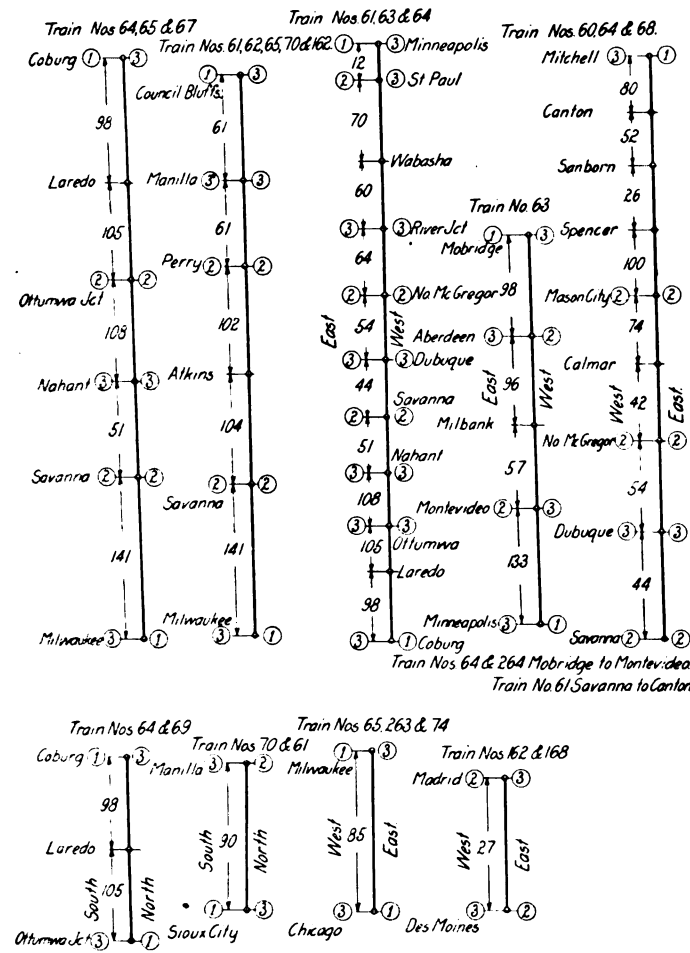

Class No. 3 inspection, otherwise termed as that attention given equipment coming into a terminal and having recently received a No. 2 inspection at least within a distance of 300 miles and where engines are changed.

Inspectors should locate themselves in their respective yards so as to have the entire train pass them, observing closely and providing remedy for pounding wheels, brake beams and connections down or loose, hot bearings, defective draft attachments and related parts and violations of federal safety appliance requirements. After defects that were discovered on the train have been remedied, inspectors must proceed to make further inspection if time will permit.

INSPECTORS LOCATED AT ISOLATED STATIONS AND LARGE MANUFACTURING PLANTS.

There are many points on the system, especially at large terminals, such as the Dearing plant of the International Harvester Company at Chicago; Montgomery Ward & Co., Chicago; Solvay Coke Plant at Milwaukee; the Washburn-Crosby Co. at Minneapolis; packing plants at Sioux City, Omaha, St. Paul, Spokane; cereal mills at Cedar Rapids, etc., where high class competitive freight is loaded and received. Cars are made empty and unless carefully watched are apt to be reloaded out on our line in defective condition, due to defective running gear or improper body construction for loading with some other commodity, both opening an avenue to damage claims and excessive delay en route.

Adequate words could not be found in praise of car inspectors who do their whole duty at points like these, where

tion and repair of all air brakes and care and attention to lubrication and packing, which as a rule is handled in about three to five minutes to a car.

METHOD TO BE FOLLOWED IN MAKING INITIAL INSPECTION.

The inspectors on the string as it reaches the receiving yard are two ground men, one roof man and two following-up men, and, where the interchange demands it, the same number starting from each end of the string, except the roof man. At this time inspection is made for all handling line defects under existing requirements, repairing all yard defects, such as nuts on box bolts, carry irons, column bolts, draft gear attachments, also brake connection bolts and cot- ters, brake shoes and keys, brake hangers and parts, and all connections of the hand-brake attachments. In many cases applying brake beams in the train yard is necessary in order to overcome switching any car to the shop track unless absolutely necessary. The finish of the string is then

they are away from any immediate supervision, and can assist so greatly to see that only proper cars for any specified loading are allowed to be considered for outbound movement over the railroad, and where improper methods are followed in the use of or delivery of cars, either loaded or empty, that instant report is given so that proper precautions can be taken and the remedy applied. Cars being delivered loaded when found defective on account of no door protection being provided, in accordance with M. C. B. rules, or where cars marked for rough freight are delivered on request for merchandise cars or otherwise, or any other irregularities coming to notice day by day, should never be dropped until someone has seen to it that lax methods are avoided and stopped. In order to carry such a plan out it is always well for car inspectors to commence the day by going over all cars to note especially those fit for loading, marking out any which cannot satisfactorily be loaded, assigning the various grades of equipment to meet requirements, having in mind the territory on the system where they are to be made empty, and using good judgment in assuming that they must make a round trip at least so far as their physical condition is concerned, and also that they will be fit to carry a full return load of such commodities as originate in the territory from which they are to return. It is also well to remember when desirable to get cars to home connections full knowledge of the character and direction of the prevailing loading is necessary, so that proper loaded movement may result. In carrying out the actual work on cars handled, it is well to do the inside work first, then go over the draft gear, brakes, roof, safety appliances, trucks and packing in the order named. The remarks made herein also apply equally to one-man stations at outlying points along the railroad. There is always more or less shortage of equipment, especially the better grade of cars, and where such equipment is being misused through loading with rubbish or otherwise, report must be made and the practice stopped.

(To be continued.)

BUREAU OF EXPLOSIVES PAMPHLETS

Two pamphlets, Nos. 20-I and 20-J, have recently been issued to wreck crews and car inspectors respectively by the Bureau of Explosives. Copies of the pamphlet follow and the full text of the regulations, from which the instructions are compiled, can be referred to readily by means of the reference to the Rules of the Bureau of Explosives at the end of each paragraph.

INSTRUCTIONS TO WORK CREWS.

Prevent fires at wrecks.—The most important point in handling wrecks is to prevent fires, especially if explosives or inflammables are involved. (1697, 1946.)

Remove explosives to a safe place.—All explosives, including broken packages, should be removed to a safe place, before beginning to clear a wreck. (1697.)

Prevent sparks in using tools, etc.—Every precaution must be used to prevent sparks when using tools, crane or locomotive to clear wreck. (1697.)

Saturate explosives remaining on ground.—Where probability of explosives remaining on the ground or in the wreck exists it should be saturated thoroughly with water. (1697.)

Handle dynamite with extra care.—Water on dynamites will not make it safe from shocks or blows, so that it is important that all such explosives be handled with extra care, even if wet. (1697.)

Handling fulminates in wrecks.—Mixing with wet earth makes all explosives safer to handle. In case fulminate has been scattered by a wreck, after the wreck has been cleared the wet surface of the ground should be removed and the

area saturated with fuel or lubricating oil and then covered with fresh earth. (1697.)

Keep lighted lanterns away from inflammable freight.—It is assumed that wrecks always contain leaking and damaged packages and lighted lanterns or other flames should not be taken into or near cars containing inflammable freight. (1946.)

Ventilate all cars containing inflammable freight.—All cars containing inflammable freight must be opened for ventilation and all packages protected by red labels and all cylinders of compressed gases removed to a safe place. (1,946.)

Remove yellow labeled substances.—All substances spilled from broken packages protected by yellow labels should be removed to a safe place. (1946.)

Cover inflammable liquids with dry earth.—All inflammable liquids spilled from broken packages or tank cars must be covered with dry earth before a lighted lantern, torch, or an engine is used in the vicinity. (1946.)

Handling spilled acids.—When acids are spilled in cars the floors should be covered with dry earth, swept clean and flushed with water. (1946.)

Use judgment to avoid fires.—Good judgment is necessary to avoid fires and useless sacrifice of property. (1951.)

Handle oil cars in daytime or use electric lights.—Dispense with all naked lights or fires possible when oil cars are leaking. Handle wrecked oil cars during daylight hours or use electric incandescent lights or electric flashlights. (1952.)

Keep lanterns on side from which wind is blowing.—When handling leaking tank cars having "inflammable" placards keep lanterns used for signalling on side from which wind is blowing and as high in air as possible, and keep lighted pipes, cigars and cigarettes away. The ash pan and firebox of a locomotive or steam derrick is also a source of danger. (1953.)

Drain leaking oil to prevent spreading.—Prevent the spread of oil by collecting it in any available vessels or draining it into a hole at a safe distance from track. Do not drain into sewers or streams of water. A stream of oil on the ground should be dammed and dry earth be thrown on the liquid as it collects. (1954.)

Do not drag wrecked tank cars.—Wrecked tank cars should be carefully jacked into position and should not be moved by dragging except as a last resort. All shocks and jars that might produce sparks or friction should be avoided. (1955.)

Handling leaking tank cars.—Do not transport leaking tank cars unnecessarily. Safety in short movements may be secured by attaching a vessel under small leaks. Cover tracks with fresh earth in rear to prevent fire overtaking car. Allow no smoking and keep engines away. If traffic is not obstructed contents of leaking tank cars should be transferred. (1956.)

Keep lights away from empty tank cars.—Keep lights away from empty or partially empty tank cars. (1957.)

Do not use water to quench oil fires.—When oil catches fire it should be smothered if possible by the use of earth, steam or wet blankets. Water will not quench an oil fire. (1958.)

Leaks at bottom outlet valves.—Leaks at unloading valves may possibly be stopped by removing the dome cover on top of tank and by moving the valve-rod handle in the dome back and forth a few times. (1959.)

Dome covers must not be removed while pressure exists.—Do not remove dome covers of tank cars containing inflammable liquids until satisfied, by lifting safety valve, that no pressure exists in tank. (1959.)

Keep trespassers away.—Guards should be placed to keep trespassers at a safe distance. (1955, 1956.)

SUGGESTIONS TO CAR INSPECTORS

Special inspection of cars necessary before loading explosives.—Certified cars to be used for explosives, must be carefully inspected inside and outside to see that the roof and sides have no loose boards, holes, or cracks, or unprotected decayed spots liable to hold sparks and start a fire; that the king bolts or draft bolts are properly protected, and that there are no uncovered iron or nails projecting from the floor or sides of the car which might injure packages of explosives; also that the floor is in good condition and has been cleanly swept before the car is loaded and that the journal boxes have been examined and that they are properly covered, packed and oiled, and that the air brakes and hand-brakes are in condition for service. (1661, 1662.)

Car certificates necessary.—Car certificates certifying to the proper condition of the car must be executed in triplicate by the car inspector. (1665.)

Inspection of explosives from connecting lines required.—Certified cars, containing explosives, when offered in interchange, must be carefully inspected by the receiving line and must not be forwarded until all violations have been corrected. Lading should also be inspected if practicable and it must be inspected when the car shows evidence of rough treatment. Only electric lights should be used when inspection is made after daylight hours. (1654.)

Company material not exempt.—Company material and supplies must be handled in accordance with the regulations. (1404, 1704.)

Inspect explosive cars frequently, and give notice if set out.—Cars containing explosives must be inspected at every opportunity to guard against hot boxes or other defects. When set out short of destination notice must be given, and all precautions taken to guard against accidents. (1690.)

Stenciling on tank cars necessary.—Tank cars must comply with M. C. B. specifications and must be stenciled to show such compliance. When not so stenciled, or if leaking, or any defects that would make leakage during transit probable, they must not be used for the transportation of any of the inflammable liquids. (1822-d.)

Inspection of loaded tank cars.—Loaded tank cars tendered for shipment must be inspected by the carrier to see that they are not leaking; tanks must be loaded with outlet valve caps off, and it is recommended that these caps be allowed to remain off until the car inspector passes on the car. Outlet valves must not permit more than a dropping of the liquid with the valve caps off. The inspector must also see that air and hand-brakes, journal boxes, trucks and safety appliances are in proper condition before accepting the car. (1822-e, f.)

Safety valves on tank cars.—Safety valves on tank cars used for the shipment of inflammable liquids whose flash-point is below 20 deg. F. must be set to operate at 25 lb. per sq. in., and the tank must be stenciled to show the pressure and date of test. (M. C. B. Rules; 1822-g, 1824-j.)

Dome placards.—The shipper must attach to the dome of all tank cars loaded with casing head or absorption gasoline, blended or unblended, three special white dome placards, one on each side of the dome and one on the dome cover. These cars also require four inflammable placards. (1824-k.)

Keep lights away from empty tank cars.—Lighted lanterns or other naked lights must not be used to examine the interior of empty tank cars. Only incandescent electric lights should be used for this examination. (1903-b.)

Dome covers and valve caps required on empty tank cars.—Empty tank cars should not be moved unless outlet valve caps and dome covers are securely placed in the proper position.

Inflammable liquids permitted in ordinary tank cars.—Gasoline, casing head gasoline, or any other inflammable (1903-c.)

liquids with flash points lower than 20 deg. F. may be shipped in ordinary tank cars that have been tested with cold-water pressure of 60 lb. per sq. in., and so stenciled, provided that the vapor tension of the liquid does not exceed 10 lb. per sq. in. (1824-j.)

Description of casing head products.—Casing head gasoline may be described as gasoline, casing head gasoline or casing head naphtha when the vapor pressure does not exceed 10 lb. per sq. in., but when the vapor pressure exceeds 10 lb. per sq. in. it must be described as liquified petroleum gas. (1824-k.)

Liquified petroleum gas permitted in insulated tank cars.—Liquid petroleum gas of vapor pressure, not exceeding 15 lb. from April 1 to October 1, and 20 lb. from October 1 to April 1, when shipped in tank cars must be shipped in special insulated tank cars approved by the M. C. B. Association. (1824-k.)

Guard against hot journals on inflammable cars.—Cars bearing "inflammable" placards and cars adjacent to them must be watched with extra care to discover hot journals, and every possible precaution taken to avoid igniting vapors when leakage is discovered. (1908.)

Stop leaking tank cars and keep lights away.—All unnecessary movement of tank cars discovered leaking in transit loaded with an inflammable or corrosive liquid must be stopped, and the unsafe condition corrected. Lanterns or other naked lights must be kept away from cars protected with inflammable placards and on the side from which the wind is blowing and as high in the air as possible. Electric lights should be used whenever practicable. Good judgment is necessary to avoid fires and useless sacrifice of property. (1909, 1951, 1953.)

Handle oil cars in daytime or use electric lights.—Naked lights or fires should not be used when oil cars are leaking. Wrecked oil cars should be handled during daylight hours, or electric incandescent lights, or portable electric flashlights used. (1952.)

Drain leaking oil to prevent spreading.—To prevent the spread of oil, it should be collected in any available vessels or drained into a hole at a safe distance from the track. It should not be drained into sewers or streams of water. A stream of oil on the ground should be dammed and dry earth thrown on the liquid as it collects. (1954.)

Do not drag wrecked tank cars.—Wrecked tank cars should be carefully jacked into position and should not be moved by dragging, except as a last resort, and all shocks and jars that might produce sparks or friction should be avoided. (1955.)

Handling leaking tank cars.—Leaking tank cars should not be moved unnecessarily. Safety in short movements may be secured by attaching a vessel under small leaks. Covering the tracks with fresh earth in rear will prevent the fire from overtaking the car. No smoking should be allowed and engine must be kept away. If traffic is not obstructed contents of leaking tank cars should be transferred. (1956.)

Keep lights away from empty tank cars.—Lights must be kept away from empty or partially empty tank cars or any care bearing inflammable placards. (1957, 1908-b.)

Do not use water to quench oil fires.—When oil catches fire it should be smothered if possible by the use of earth, steam or wet blankets, as water will not quench an oil fire. (1958.)

Leaks at bottom outlet valves.—Leaks at unloading valves may be stopped by removing the dome cover on top of the tank and by moving the valve-rod handle in the dome back and forth a few times. (1959.)

Release pressure before removing dome covers.—Dome covers of tank cars containing inflammable liquids should not be removed until no pressure exists in the tank, which should be ascertained by lifting safety valves. (1959.)

Stop "blowing" safety valves by cooling shell.—When the "blowing" of safety valves of a tank car is noted the car should be sprayed with water or any other possible means of cooling the shell of the tank should be used. (1912-d.)

Keep trespassers away.—Unauthorized persons must be

kept away from explosives and other dangerous articles. (1643-b, 1871-d.)

Report violations.—Violations of the rules, such as defects of cars containing explosives, tank cars that do not comply with M. B. C. Rules or other requirements, etc., must be reported. (1434-a, 1715-a.)

ANNUAL REPORT OF THE BUREAU OF SAFETY

Use of Hand Brakes on Heavy Grades Condemned; Automatic Stops and Train Pipe Connectors Tested

THE report of the chief of the Bureau of Safety, which was recently issued is of particular interest this year, as it contains, in addition to the usual review of the safety appliance inspection work, important recommendations regarding air-brake maintenance and the operation of trains on heavy grades. The following is an abstract of the portions of the report dealing with these questions.

The table below affords opportunity for ready comparison of the results of inspections with previous years. It has been compiled from the principal figures for the fiscal years ended June 30, from 1915 to 1919, inclusive:

	1915	1916	1917	1918	1919
Freight cars inspected	1,000,210	908,566	1,100,104	1,059,913	1,023,942
Per cent defective...	4.77	3.72	3.64	3.92	3.7
Passenger cars inspected	33,427	27,220	29,456	25,732	23,712
Per cent defective.....	2.85	1.82	0.85	0.56	0.39
Locomotives inspected.	38,784	31,721	37,199	33,806	30,707
Per cent defective.....	4.06	3.66	2.69	2.18	1.84
Number of defects per 1,000 inspected	27.23	45.56	41.16	44.01	40.92

As shown by this summary, there was a decrease for the past year in the percentage of defects found on all classes of equipment inspected, namely, freight cars, passenger cars and locomotives; the number of defects per 1,000 cars and locomotives inspected is the lowest in the history of safety appliance inspection. For the past five years this percentage has been maintained at a low figure, but nevertheless the reports for the last fiscal year indicate a marked improvement in the general condition of safety appliance equipment.

An analysis of the figures, however, shows that of a total of 44,129 defects, comprising 244 distinct classes of defects, 22,275 were defects to visible parts of air brake apparatus, and of these 20,283 represent but 5 classes, viz.: air brake cut out, 7,124; cylinder and triple not cleaned within 12 months, 6,258; train pipe loose, 1,802; release rod missing, 3,258; and retaining pipe defective, 1,841. In other words, more than half of the total number of defects reported during the year were due to defective air brakes, 91 per cent of which were confined to five visible parts. It is apparent, therefore, that it is entirely practicable to effect a material improvement in the condition of safety appliance equipment. The remedy for this condition lies in more thorough inspection by the carriers themselves and prompt repair of defective equipment. Inasmuch as only a small percentage of cars and locomotives in service remains to be equipped in accordance with the safety appliance standards prescribed by the commission's order of March 13, 1911, the carriers will be in position to devote greater effort toward maintaining safety appliances in proper condition, and in future years still further decrease in the percentage of defects is confidently expected.

In the investigation of the condition of air brakes on trains as they left terminals after terminal or standing tests have been made by the commission's inspectors. Tests of 1,196 trains were made, aggregating 41,846 cars. In these trains

there were but six non-air cars; there were 330 cars with their brakes cut out, and 1,947 on which the brakes did not apply; in the trains tested, the brakes were operative on an average of 93 per cent of the cars.

During the year, evidence of violations of the safety appliance laws by railroads operated under federal control has not been filed with United States district attorneys for prosecution, but such evidence has been furnished to the United States Railroad Administration to enable it to take corrective measures. In connection with the consolidation and unification of terminal facilities effected by the Railroad Administration, investigations conducted by this bureau have disclosed that in some instances proper inspection was not being given equipment in such terminals, and available repair facilities were not being sufficiently utilized to insure that cars having safety appliance defects would not be moved in violation of law. Several cases of this character were called to the attention of the Railroad Administration, and in each case, sometimes after conferences between representatives of this bureau and the railroad companies involved, proper corrective measures were taken so as to secure compliance with the requirements of law. The Railroad Administration has co-operated with this bureau to the fullest extent, to the end that safety appliance conditions be improved, and that the requirements of the safety appliance law be fully observed, and a marked increase during the year in the effectiveness of the administration of the safety appliance law has resulted.

Notwithstanding the requirement of law that trains must be controlled by power brakes without the use of hand brakes for that purpose, situations exist on several railroads in different parts of the country where trains are still controlled on mountain grades by means of hand brakes. Measures are being taken by this bureau, with the co-operation of the Railroad Administration, to bring about the discontinuance of this practice and to secure full compliance with the law. In some cases of this character, joint investigations have been conducted by this bureau and the railroad companies involved for the purpose of fully establishing what the present operating conditions are and what facilities are available for inspecting, testing, and repairing air-brake equipment. Demonstrations have then been conducted to show that it is both practicable and safe to control trains on these grades by means of power brakes, as required by law. These demonstrations consist of placing air-brake equipment on a number of trains in proper operating condition, and then operating these trains down the mountain grades in question, controlling the speed solely by the use of power brakes. In each case, a sufficient number of demonstrations of this character have been conducted to satisfy fully all concerned that operating practices conforming to the requirements of the law are feasible, and measures have then been taken by the Railroad Administration to place these practices in effect. Investigations and demonstrations of this character have already been conducted on the Baltimore & Ohio and

the Philadelphia & Reading, and investigations of operating practices on mountain grades of other railroads are now in progress. The investigations made have demonstrated that all that has been necessary was proper maintenance of air-brake equipment, as well as instruction and education of railroad employees in its proper use under the conditions existing on such grades.

These instances, together with the results of safety-appliance inspections during the past year, again direct attention to the fact that improvement in the condition of air-brake equipment and in air-brake operating conditions is one of the urgent demands of railroad service at the present time.

The order of the Commission of June 6, 1910, requires:

That on and after September 1, 1910, on all railroads used in interstate commerce, whenever, as required by the safety appliance act as amended March 2, 1903, any train is operated with power or train brakes, not less than 85 per cent of the cars of such train shall have their brakes used and operated by the engineer of the locomotive drawing such train, and all power brake cars in every such train which are associated together with the 85 per cent shall have their brakes so used and operated.

The minimum percentage requirement established by this order is generally understood and recognized, and it is an infrequent occurrence that a train is hauled from a terminal having less than 85 per cent of the cars equipped with power brakes in operative condition. However, in addition to the minimum percentage requirement specified, the order also reiterates the provision of law that all power-brake cars in a train which are associated together with the specified minimum percentage shall have their brakes used and operated. Railroad companies have paid comparatively little attention to this maximum requirement of the law and order, and the belief is widespread and general that if a train has the prescribed minimum percentage of power-brake cars with air brakes in operation, the terms of the law are fully complied with. It is common practice at the present time for trains to leave terminals having some cars with inoperative brakes, or having brakes cut out, notwithstanding the fact that facilities are available at such terminals for making repairs or replacements necessary to place all power-brake equipment in proper operative condition.

Strict enforcement of the provision that "all power-brake cars in every such train which are associated together with the 85 per cent shall have their brakes so used and operated," as applied to trains leaving terminals or other points where facilities for making repairs are available, would result in 100 per cent operative power brakes in practically all trains leaving such points. The adoption of this practice would inevitably result in general and material improvement in air-brake conditions, as careful and thorough air-brake tests at terminals would be required as well as that more prompt attention be given necessary air-brake repairs. It would also result in reducing the number of violations of the minimum percentage requirement, for the reason that frequently trains now leave terminals with barely 85 per cent of the cars having power brakes in operative condition, and if the brake equipment on additional cars becomes defective en route, or if cars with defective brakes are picked up, or if cars with good brakes are set out, the train then has less than the required 85 per cent.

The adoption of this policy would go far toward meeting the complaint referred to in the last annual report, which is still frequently heard, that air-brake maintenance is neglected on roads where braking conditions are less severe than on roads having steep mountain grades, thereby imposing an excessive burden on the air-brake inspection and repair forces of the latter roads.

As stated in the annual report of this bureau for last year, notwithstanding the adverse decision of the Circuit Court of Appeals for the Fourth Circuit in the Chesapeake & Ohio case, it is believed that a proper interpretation of the law requires that the air brakes of all cars in every train which

have been equipped with power brakes, as distinguished from non-air cars, and which are associated with cars having operative power brakes, must be in operative condition and must be used by the engineer of the locomotive drawing the train. The ground upon which the minimum percentage was prescribed was that there were numerous cars in service which had not been equipped with power brakes, and provision should be made for continuing them in service until they could be equipped. It is clearly evident that the maximum requirement of the law and the Commission's order is a progressive one, making it obligatory upon the carriers to use air brakes in an increasing ratio until all cars are equipped; and the provisions are mandatory that when all cars in train are equipped with power brakes, all such brakes must be used by the engineman of the locomotive hauling the train.

In addition to terminal tests of trains made up for departure, more general adoption of the practice of conducting air brake tests on trains when arriving at terminals is also advocated. Incoming tests of this character disclose the condition of air-brake equipment in time to permit of necessary repairs and adjustments being made without delaying trains made up and ready for departure, as well as eliminating switching for the purpose of setting out cars with defective brakes.

The air-brake provision of the law has again been passed upon by the Supreme Court of the United States in the case of Louisville & Jeffersonville Bridge Co. v. United States, involving the movement of transfer trains from one yard to another, crossing city streets at grade and using the main-line track for a distance of at least 2,600 feet, without the specified minimum percentage of power brakes being in use. In this case the court stated that it would be difficult to imagine a movement in which the control of the cars by train brakes would be more necessary, notwithstanding that the street crossings were protected by gates and the main-line movements were watched over by a yardmaster from an elevated tower. It was also stated that the absolute duty to comply with the law is not excused by carefulness to avoid the danger which the appliances prescribed were intended to guard against, nor by the adoption of what might be considered equivalents of the requirements of the act.

This same provision has also been interpreted by the Circuit Court of Appeals for the Fifth Circuit in two cases involving the movement of transfer trains in and about the city of Galveston for several miles, crossing main-line tracks of several railroads and streets at grade, and for parts of the distance over main-line track as well as a network of tracks comprising the city yards, without the specified minimum percentage of power brakes being in use. It was held that the movements in question were not switching operations, but train operations to which the law applies. It was also held that the fact that there were switching operations before the movements were completed did not have the effect of making the entire movements such as do not come within the prohibition of the statute.

INVESTIGATION OF SAFETY DEVICES.

During the year plans of 80 devices were submitted for consideration; 74 devices were examined and opinions thereon transmitted to the proprietors. Of the number examined, 57 were so impracticable or crude that they were considered practically worthless; seven were devices which were not intended primarily to promote safety in railway operation, and 10 possessed elements of merit which warranted further development or practical tests to prove their utility. In addition, revised plans of 15 devices which had been previously examined were submitted for further consideration, and all of these plans were examined and reported upon; four of these latter devices were commended to the extent

of warranting further development or trials under service conditions. Among the devices upon which favorable reports were made, there were eight automatic train-control devices, five brake devices or attachments and one railroad tie.

During the year tests were conducted of the automatic train-control system submitted by the National Safety Appliance Company, San Francisco, Cal. This device is of the magnetic induction type employing permanent magnets in both track and locomotive equipment, as well as an electromagnet on the track for nullifying or neutralizing, when desired, the effect of the permanent track magnet. Tests were made on the Western Pacific and the Southern Pacific Railroads from March to June, 1919, and a report upon this device was transmitted to Congress by the Commission under date of June 30, 1919, this report being printed as House Document No. 139, Sixty-sixth Congress first session. The following conclusion is stated in that report:

While as a whole the tests made are not considered conclusive, it has been demonstrated that, with the exception of one of the locomotive-control valves used in the tests, the locomotive apparatus, so far as could be determined, operated as intended, and whenever actuated by the track-magnet impulse it accomplished the functions for which it was designed; further, that the transmission of a magnetic impulse from a permanent magnet installed

on the track to locomotive apparatus designed to be controlled and actuated thereby is both practical and feasible. The fundamental principles upon which this system is based have therefore been demonstrated to be sound and practicable, but the available working limits, as well as the reliability of the transmission and control of the actuating impulse, remain to be fully established. For these purposes further development work, as well as more extended trials under practical service conditions, is necessary.

Tests have also been conducted of the automatic train-pipe connector submitted by the American Connector Company, Cleveland, Ohio. This device is in use on the Copper Range and tests were made in July and August. A report upon this device was transmitted to Congress by the commission. The conclusion stated in this report is that the use of this automatic connector on the Copper Range materially reduces the hazards to which trainmen are subjected as it almost entirely eliminates the necessity for men to go between the cars of connector-equipped trains. The device tested possessed some features which were not fully applicable to general railroad operating conditions, but the results of the tests and its use on that road warrant its further development for the purpose of more fully meeting the requirements of an automatic train-pipe connector for general railroad service.

COMPARATIVE TESTS OF REFRIGERATOR CARS

Temperature Readings in Actual Service on Cars Equipped with Overhead and End Ice Bunkers

THE object of this test was to investigate the comparative refrigerating performance of a car equipped with overhead ice tanks and one equipped with collapsible end ice tanks. Both cars were pre-iced and loaded with Tokay grapes and were handled under standard refrigeration from Lodi, Cal., to Chicago, Ill.

The equipment used in the test consisted of Santa Fe refrigerator car SFRD 12646 and Chicago Great Western refrigerator car 30000. SFRD 12646, Class U, was built in the winter of 1917-18, and is equipped with Santa Fe standard collapsible bulkheads (Bohn Syphon) without floor racks. Car GGW 30000 was built in the fall of 1915, and in the spring of 1919 it was reinsulated to make the insula-

tion made in order that the test could be conducted this season. The results of the test as regards temperature, air circulation and refrigeration would not be affected by this temporary installation. Car GGW 30000 is equipped with six overhead basket ice tanks of the Moore type and with floor racks.

The following table shows the principal dimensions of the two cars under test:

	CGW 30000	SFRD 12646
Loading capacity.....	60,000	60,000
Outside length.....	40 ft.	41 ft. 3 in.
Inside dimensions—		
Length	37 ft. 10 3/4 in.	33 ft. 2 1/4 in.
Width	8 ft. 2 in.	8 ft. 2 3/4 in.
Height floor to ceiling.....	7 ft. 8 1/4 in.	7 ft. 3 in.
Height racks to ceiling.....	7 ft. 3 3/4 in.
Height racks to ice tank	5 ft. 11 1/2 in.

TABLE I—COMPARISON OF TEMPERATURES, IDENTICAL LOCATIONS, CARS, GRAPE UNDER REFRIGERATION, SFRD 12646 vs. CGW 30000

Table with columns for Therm. No. 3 through 12, and Therm. No. 10 and 11. Each column contains CGW and SFRD values. The table lists 12 bulb locations and an average row.

APPARATUS.

The temperature observations taken in the cars throughout the test were obtained by means of Leeds & Northrup resistance type electrical thermometers obtained from the U. S. Department of Agriculture, Bureau of Markets, and were calibrated, previous to installing in the test cars, by means of an ice bath. The locations of the bulbs for recording the temperature of the lading are given in the footnotes to Table 1. A balanced indicator was used for reading the car temperature from the outside, so that it was not necessary to open the doors en route to obtain the temperatures of the fruit.

The amount of ice used in each car during the test was

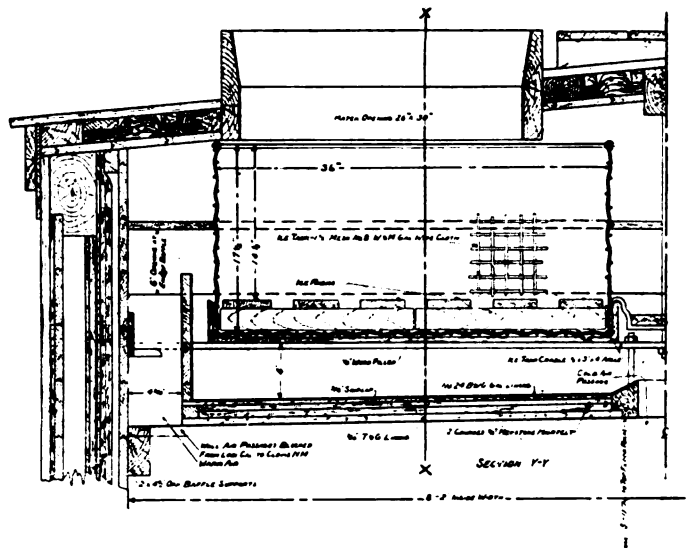

Fig. 2. Cross Section Through Overhead Tank, C. G. W.-30,000

estimated from full cakes of artificial ice in order to more accurately determine the amount. Outside temperatures throughout the test were obtained by means of mercury thermometers, read as often as practicable. The resistance bulbs were located in the head end of each car only. No temperature readings were taken in the rear half of the test cars.

METHOD OF TESTING.

After the cars were selected at Calwa, Cal., they were forwarded dry to Stockton, Cal. At Stockton CGW 30000 had

- 1. Temperature of air at top of floor rack, center of car, 12th stack, center row.
2. Temperature of air coming out of cold air passage in overhead baffle, center of car, 12th stack.
6. Fruit temperature top box grapes, 1st stack next end of car, center row.
4. Fruit temperature of bottom box grapes, 8th stack, center row.
5. Fruit temperature top box grapes, 4th stack, center row.
6. Fruit temperature top box grapes, 1st stack next end of car, center row.
7. Fruit temperature, top box grapes, 1st stack next end car, center row.
8. Fruit temperature bottom box grapes, 4th stack, center row.
9. Fruit temperature top box grapes, 8th stack, center row.
10. Air temperature in warm air passage at end of baffle, center row.
11. Fruit temperature bottom box grapes, 12th stack, center row.
12. Fruit temperature 5th box grapes above floor, 12th stack, center row.
Bulb No. Location
CAR CGW 30000 Location
CAR SFRD 12646 Location
1. Temperature of air at floor, center of car, 11th stack, center row.
2. Temperature of air below ceiling, geometric center of car.
3. Fruit temperature top box grapes, 11th stack, center row.
4. Fruit temperature bottom box grapes, 7th stack, center row
5. Fruit temperature top box grapes, 4th stack, center row
6. Fruit temperature bottom box grapes, 1st stack, next bulkhead, center row.
7. Fruit temperature top box grapes, 1st stack next bulkhead, center row.
8. Fruit temperature bottom box grapes, 4th stack, center row.
9. Fruit temperature top box grapes, 7th stack, center row.
10. Air temperature at top of bulkhead opening, warm air returning to ice tank.
11. Fruit temperature bottom box grapes, 11th stack, center row.
12. Fruit temperature 5th box grapes above floor, 11th stack, center row.

the six warm air passages at the side walls blocked, as shown in Fig. 1. These passages were blocked to see if greater uniformity of temperatures could be obtained than if left open. The passages remained blocked from the time the cars were loaded at Lodi, Cal., up to Clovis, N. M., where they were all opened, thus permitting the air to circulate up the side wall passages into the ice tanks as well as through the air passage at the end of the baffle.

The cars were pre-iced at Stockton at 6 p. m. October 7 at the Santa Fe ice plant, where 10,500 lb. of ice were placed in the bunkers of SFRD 12646 and 4,275 lb. of ice in the tanks of CGW 30000. The small amount of ice furnished CGW 30000 as compared to the total ice tank capacity (6,300 lb.) was due to the poor manner in which this car was iced at that point. No salt was used in either car at any time during the test. After initial icing both cars were forwarded to the warehouse of the T. H. Peppers Company at Lodi, Cal., via the Central California Traction Company, where they were loaded on October 8.

The loading of the cars commenced at 8 a. m. and was completed at 2:30 p. m. The ends of both test cars in which the electrical thermometers were located were loaded first.

Temperature readings by means of mercury thermometers during the loading period showed that the grapes were at a temperature of 59 deg. F. in both cars.

SFRD 12646 was loaded with 1,050 standard crates of grapes, weight 29,400 lb., 10 layers high, 5 rows wide and 11 stacks long in the end in which the electrical thermometers were located, and 10 stacks long in the opposite end. CGW 30000 was loaded with 1,072 standard crates of grapes, weight 30,016 lb., 9 layers high, 5 rows wide and 12 stacks long in the end in which the thermometers were located, and 11 and 12 stacks long in the opposite end. In both test cars the regulation center bracing for grape cars was used to prevent the load shifting in transit.

Both cars were sealed at 2:30 p. m., at which time initial temperature readings of the electrical thermometers were taken. Both test cars were billed to Chicago, Ill., under standard refrigeration; routed Lodi to Stockton, Central California Traction Company, Stockton to destination, Atchison, Topeka & Santa Fe.

The temperatures of both cars, as well as the total amount of ice furnished and the outside temperatures, are shown in Table I. The following table gives the amounts of ice furnished at each icing station en route, as well as the total amounts furnished:

Location	Date	CGW 30000		SFRD 12646	
		Amount, Lb.	Total Amount, Lb.	Amount, Lb.	Total Amount, Lb.
Stockton, Cal.	Oct. 7, 1919	4,275	4,275	10,500	10,500
Stockton, Cal.	Oct. 8, 1919	1,710	5,985	1,995	13,495
Bakersfield, Cal. ...	Oct. 9, 1919	2,550	8,535	1,950	14,445
Needles, Cal.	Oct. 10, 1919	1,300	9,835	1,750	16,195
Winslow, Ariz.	Oct. 12, 1919	1,100	10,935	1,100	17,295
Belen, N. M.	Oct. 13, 1919	400	11,335	700	17,995
Clovis, N. M.	Oct. 13, 1919	800	12,135	550	18,545
Waynoka, Okla. ...	Oct. 14, 1919	1,250	13,385	1,000	19,545
Argentine, Kans. ...	Oct. 16, 1919	2,000	15,385	1,700	21,245
Corwith Yards, Chicago, Ill.	Oct. 18, 1919	500	15,885	1,100	22,345

The cars left Lodi, Cal., at 3:15 p. m. October 8 and arrived at Corwith Yds., Chicago, at 1:15 a. m. October 18, thus making the total time for the 2,470-mile trip 9 days, 9 hrs. and 55 min., or an average speed of 11.0 miles per hour.

After the cars arrived at Corwith Yards on the morning of October 18 no further temperature observations were taken. Cars were moved to the Twenty-first street yards of the Santa Fe, where the electrical thermometer equipment was removed. The cars were held at the yards for consignee's order and for inspection of the fruit by the consignee's inspectors, Santa Fe inspectors and inspectors of the Inspection Service, U. S. Department of Agriculture, Bureau of Markets.

GENERAL RESULTS.

As shown by the table above, the total amount of ice furnished SFRD 12646 was 22,345 lb. and for CGW 30000 was 15,885 lb., a difference of 6,420 lb., or 28.8 per cent in favor of CGW 30000. Both cars had the ice tanks filled to the same capacity at the final reicing at Corwith, as at the initial icing at Stockton. The total amount of ice melted in each is the difference between the total amount of ice furnished in transit and the initial icing. This gives 11,845 lb. melted in SFRD 12646 and 11,610 lb. melted in CGW 30000, or an ice rate of 47.2 lb. per hr. for SFRD 12646 and 46.3 lb. per hr. for CGW 30000.

In the end ice tank car it was necessary to keep the bunk-

Fig. 3. Cross Section of Car C. G. W.-30,000

ers full of ice in order to secure proper refrigeration, as the ice in the lower portion of the bunkers afforded very little, if any, effective refrigeration; the car equipped with overhead ice tanks had all of the ice located so as to create refrigeration, thus making it possible to carry less ice and yet obtain the same temperature.

The chart in Fig. 5 is plotted from the average of fruit temperatures taken at the bottom and top layers of fruit. Bulbs number 3, 5, 7 and 9 were averaged to show the fruit temperatures of the top layer; bulbs number 4, 6, 8 and 11 were used for averaging fruit temperatures in the bottom layer. This chart and the data in Table I, giving the temperature comparisons in both cars, show that at times there was no difference in the temperature of the fruit in the bottom and top layers of car CGW 30000; that the maximum difference was 1.4 deg. F., and the average difference was 0.4 deg. F.

The minimum difference in the temperatures of the fruit in the bottom and top layers of SFRD 12646 was 5.6 deg.

F. The maximum difference was 14.3 deg. F., and the average difference was 8.6 deg. F. The maximum difference occurred at the commencement of the test while the temperature of the fruit was being reduced.

The marked uniformity in the temperature of the fruit in

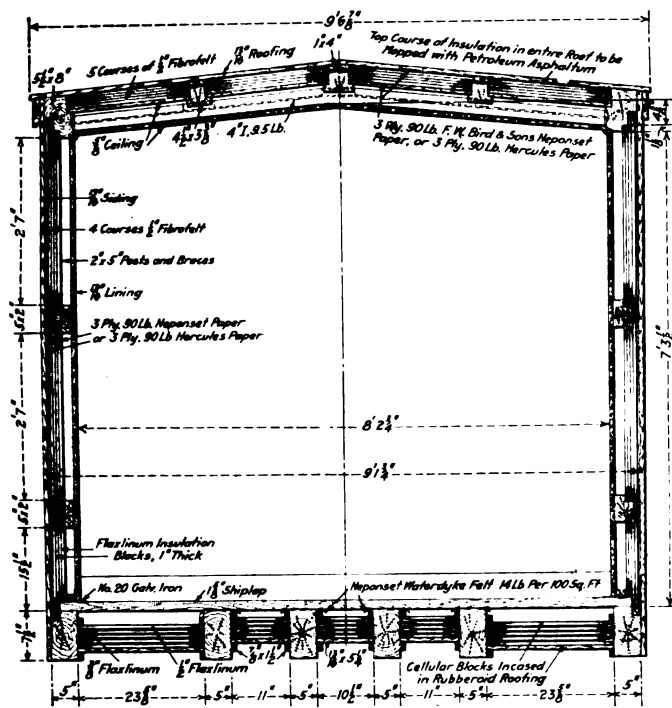

Fig. 4. Cross Section of Car A. T. & S. F.-12,646

car CGW 30000 demonstrated a uniform circulation of refrigerated air throughout the entire load. The temperature of bulb No. 2 in SFRD 12646, located six inches below the ceiling at the geometric center of the car, fluctuated consid-

refrigeration system, any heat passing through the roof of the car must have been prevented from reaching the load by its immediate absorption by the ice in the overhead tanks.

At the time the fruit was loaded its temperature was 59 deg. F. At the time the car was sealed the average temperature of the fruit in the top layer of CGW 30000 was 58.0 deg. F. and in the bottom layer 56.6 deg. F. The temperature in the top layer of SFRD 12646 was 59.8 deg. F. and in the bottom layer 52.0 deg. F. This shows that the fruit in the bottom layer of the latter car had cooled 7.0 deg. F.; while the fruit in the top layer had increased 0.8 deg., that the fruit in the top and bottom layers of CGW 30000 was cooled 1.0 deg. and 2.4 deg., respectively. At destination the average fruit temperature of the top layer in CGW 30000 was 38.9 deg. F. and the bottom layer 38.5 deg. F., a difference of 0.4 deg. In SFRD 12646 the average temperature at destination in the top layer was 41.6 deg. F. and in the bottom layer 36.0 deg. F., a difference of 5.6 deg.

The top layer of fruit throughout the test averaged 47.7 deg. F. for SFRD 12646 and 44.7 deg. F. for CGW 30000, or 3.0 deg. lower in car CGW 30000 than SFRD 12646. The temperature at the lower layer in SFRD 12646 is affected by the cold air coming directly off the ice, which accounts for the lower temperatures of this layer.

The bottom layer of fruit throughout the test averaged 44.3 deg. F. for CGW 30000 and 39.1 deg. F. in SFRD 12646, or 5.2 deg. lower in SFRD 12646 than CGW 30000. No effect was noticed in the temperatures throughout the load in CGW 30000 when the side wall air passages were either blocked or left open.

ICING IN TRANSIT.

In constructing CGW 30000 with the improved overhead icing system several changes were made in order to secure maximum refrigeration and uniform circulation throughout the car. The car had previously been equipped with six hatches; these were not altered to instal the six overhead ice tanks. The hatches were not originally designed to be used

Fig. 5. Range of Temperature and Ice Furnished During Refrigeration Test

erably and was affected more by the outside air temperatures than any other thermometer, as shown in Table I. This fluctuation was due to the heat passing through the roof of the car, affecting the air furthest from the ice tanks. Due to the location of the ice in the car equipped with the overhead

with the ice tanks, as finally installed in the car, and difficulty was encountered during the test in icing this car; considerable more time was required to properly ice this car than the other test car equipped with end ice tanks.

The objectional feature in icing this car can be overcome

by using tanks setting transversely and lengthening the hatchways, so that each tank can be iced from two hatchways. The construction and insulation of CGW 30000 with the overhead ice tanks are shown in Figures 1, 2 and 3.

INSPECTION AT CHICAGO.

Three separate inspections of the grapes in the two test cars were made at the yards of the Santa Fe by consignee's inspectors, by Santa Fe inspectors and by government inspectors of the Inspection Service, Bureau of Markets, U. S. Department of Agriculture.

The consignee's inspection report showed that the grapes in SFRD 12646 were decayed and moulded much more than those in CGW 30000, the difference in the quality of the grapes in the two cars being great enough to cause the consignee to unload those in SFRD 12646 at Chicago and to divert CGW 30000 on to New York market.

The Santa Fe's inspection report showed "slight decay and mould in CGW 30000, some decay and mould in SFRD 12646, four crates in top layer near doorway slightly wet, caused apparently by leak from roof." These statements infer that the grapes in CGW 30000 were in better condition than those in SFRD 12646 and corresponds to the condition found by consignee's inspectors.

The reports from the Inspection Service of the Bureau of Markets, U. S. Department of Agriculture, are as follows:

SFRD 12646—Stock well packed, highly colored, and presents attractive appearance; a few mouldy berries scattered through top half of load, as noted above (top 5 layers crates, balance of load practically no decay). Impossible to inspect entire car without unloading; certificate restricted to one stack crates next bracing, each end of car. Temperature top of door 46 degrees F., bottom 42 degrees F.

CGW 30000—Decay in this car slightly in excess of that in car SFRD 12646. Stock well packed, highly colored, a few scattered mouldy berries, showing very good appearance. impossible to inspect entire car without unloading; certificate restricted to one stack crates next bracing, each end of car. A few mouldy berries scattered throughout most crates, also many berries showing slight mould at stems. Temperature at top of door 42 degrees F., bottom 40 degrees F.

It does not seem that the consignee would have diverted CGW 30000 to New York and unladen SFRD 12646 if the inspection as shown by government inspectors had been true. The temperatures shown by the government inspection report at the door was 4 deg. lower at the top in CGW 30000 than in SFRD 12646 and 2 deg. lower at the floor of the car, notwithstanding their claim of there being less decay in SFRD 12646.

The four crates, "slightly wet," referred to in the Santa Fe inspection report, resulted from condensed moisture dripping from four baffle supporting bolts which were not properly protected.

CONCLUSIONS.

1. Car CGW 30000, equipped with overhead ice tanks, was furnished with 28.8 per cent less ice than car SFRD 12646, equipped with end ice tanks.

2. At times there was no difference in the temperature of the fruit in the top and bottom layers of car CGW 30000; the maximum temperature difference was 1.4 deg.; the average temperature difference was 0.4 deg.

3. The minimum temperature difference of the fruit in the top and bottom layers of car SFRD 12646 was 5.6 deg.; the maximum temperature difference was 14.3 deg.; the average temperature difference was 8.6 deg.

4. The fruit in the top layer of CGW 30000 throughout the test averaged 44.7 deg. F. and that in SFRD 12646 averaged 47.7 deg. F., or 3.0 deg. higher than in the same layer of CGW 30000.

5. The fruit in the bottom layer of CGW 3000 through-

out the test averaged 44.3 deg. F. and that in SFRD 12646 averaged 39.1 deg. F., or 5.2 deg. lower than in the same layer of CGW 30000.

6. The temperatures in test car CGW 30000 showed that the air circulation was practically uniform throughout the entire load, giving substantially uniform temperatures in all the crates of grapes.

7. The temperature in test car SFRD 12646 showed that the air circulation was not uniform throughout the load, causing an extremely wide variation of temperatures in the grapes in the bottom and top layers.

8. The time required for icing CGW 30000 was considerably greater than SFRD 12646, but by changing the design of the ice tanks and hatches practically the same time would be required for icing both cars.

9. The condition of the grapes in CGW 30000 was much better than in SFRD 12646, the percentage of decayed grapes running much higher in SFRD 12646 than in CGW 30000.

10. Consignee's inspection reports on the condition of the grapes in the two test cars upon arrival in Chicago warranted them forwarding CGW 30000 on to New York market and in their unloading those in SFRD 12646 on the Chicago market.

11. The inspection report on the condition of the grapes in the test cars upon arrival in Chicago, made by the Inspection Service of the Bureau of Markets, U. S. Department of Agriculture, was superficial, since only one stack of crates in each end of car was inspected, and was contradictory to the other reports, both of which showed less decay in CGW 30000 than in SFRD 12646.

12. On the whole, the test showed the performance of CGW 30000 to be superior to SFRD 12646, since it used less ice, gave a substantially uniform temperature throughout the entire car and carried the load in better condition than the other car.

This test was made by G. J. Congdon, supervisor fuel and refrigeration, Chicago Great Western, and witnessed by Lester W. Collins, mechanical engineer, Refrigerator Heater & Ventilator Car Company, St. Paul, Minn. The test was made possible through the co-operation of the shippers, T. H. Peppers Co.; consignee, Crutchfield, Woolfolk & Clore; the officials and employees of the Santa Fe Refrigerator Dispatch Co., and Santa Fe Railroad. The Bureau of Markets, U. S. Department of Agriculture, Washington, D. C., loaned sufficient electrical thermometer equipment for conducting the test.

Scene on the South African Government Railways

SHOP PRACTICE

GANG CUTTERS FOR PISTON RINGS

In the operation of a railroad repair shop there are many ways in which economies can be effected, and in no other way can more be done in this respect than in the many small jobs on machines.

A rapid and economical means of cutting piston rings on a boring mill has been devised in the Canadian Pacific shops and is illustrated in the accompanying drawings. The device consists of a holder *A*, in which are inserted four cutters *B*, each having an individual collar *C*, all secured in the holder by the bolt or pin *D*. The cutter *B* is provided with a $\frac{3}{8}$ -in. hole so located as to coincide with any one of a series of similar holes through the collar *C*, by means of which the cutter can be secured in any position that may be desired, by inserting the pin *E* in the holes. The collars are provided with teeth which mesh with similar teeth on the pinion *F*. Adjustment of the cutters may be obtained

Details and Assembly of Piston Ring Gang Cutters

by a movement of the rack *G*, which also has teeth meshing with the pinion *F*. After the cutters are adjusted to the position the set screw *H* is tightened, thus securing the cutters in the desired position.

As will be seen from the drawings, the cutting edges of the cutters *B* may easily be ground without any decrease in the diameter of the cutter and, consequently with no change in the thickness and spacing of the cutting edges. The particular cutters illustrated were designed for piston rings $\frac{3}{8}$ in. thick, but the idea may be adapted to any size desired, or if conditions make it necessary, the number of rings cut at one operation may be increased or decreased as may be advisable.

The use of this device has permitted a considerable economy in the Canadian Pacific shops. Its advantages are obvious, as the high cost of labor at the present time makes it necessary to utilize machines and men to their full capacity.

MACHINING VALVE PACKING STRIPS

BY A. W. C.

The proper machining and fitting of the packing strips used in balanced slide valves is of great importance, as any leakage of steam by these strips is a total waste. New men when given the short strips to shape are often puzzled as to the best way to machine them, as they are difficult to get at to caliper. Usually the surface *A* between the lugs is finished first on a shaper, surfaces *B* and *C* being shaped at the same time and care being taken that surfaces *C* are finished with

Typical Diagram of Valve Strip

the tool set at the same depth as when finishing surface *A*. The strip is then laid with surface *A* or surfaces *B* on a parallel and machined on surface *D*. The strips are calipered at either or both ends with more or less satisfactory results. The necessity of having surfaces *C* finished exactly in line with surface *A* is here seen, otherwise incorrect calipering results. When cutting surface *D* it is necessary to take a cut over far enough to get the calipers on, and it is this cutting and calipering that is the time consuming operation, especially when a large number of strips are machined.

The following is a method of machining packing strips that has been used with excellent result. The indicating

Type of Caliper Used for Gaging Thickness

caliper or gage illustrated is first lightly clamped to a tool shank by a small clamp and used as an indicator would be to determine if the parallel is really parallel with the shaper ram's travel. Any discrepancies are remedied by tissue paper liners. The parallel used is of a length that will allow the strip to be placed with surface *A* on it (about seven inches long), this surface having been finished first. No particular

care is given surfaces *B* or *C*, which eliminates one time-consuming feature. The valve groove is then measured with the calipers by tapping the solid leg until the indicator registers on any graduation, the graduation being noted. A broad-nosed tool is held in the tool post, the tool having a small flat ground on it, as illustrated. The caliper is placed be-

tween the parallel and tool and the tool is adjusted vertically until the indicator shows that the tool is a distance from the parallel equal to the width of the groove in the valve; that is, the indicator points to the same graduation as it did when in the groove. The vertical micrometer collar is now set at zero and a roughing cut taken over the strip which is held on the parallel by a pair of shaper hold-downs. A finishing cut is next taken after feeding the tool down a few thousandths. Once having decided how many thousandths to run the tool down, it is an easy matter to fit all strips uniformly, as each strip can be made any desired number of thousandths smaller than the grooves. The filing and spotting of the strips is thus reduced to a minimum, which saves 25 to 50 per cent on the machining time.

PRESSURES FOR MOUNTING WHEELS AND APPLYING CRANK PINS

BY JAMES PARTINGTON
Estimating Engineer, American Locomotive Company

In locomotive and car construction, it is the general practice to use hydraulic pressure for mounting wheel centers on axles, applying crank pins, etc. The different operations involved may be classified as follows:

1. Mounting cast iron driving wheel centers.
2. Mounting cast steel driving wheel centers.
3. Applying crank pins in cast iron driving wheel centers.
4. Applying crank pins in cast steel driving wheel centers.
5. Mounting cast iron truck wheel centers.
6. Mounting cast steel or wrought steel truck wheel centers.
7. Mounting cast iron chilled tread truck wheels.
8. Mounting cast steel or rolled steel truck wheels.

Very little information seems to be available in printed form to indicate the pressures which should be used for these different operations and the following table showing the practice of the American Locomotive Company has been found by long experience to give satisfactory results. The basis of this table as worked out for operations, (1) and (3), was the commonly accepted formula for cast iron centers which calls for 10 tons pressure per inch of diameter of the shaft. These pressures have been consistently adhered to for cast iron driving wheel centers, having been amplified only to the extent of permitting a minimum pressure of 10 per cent less and fixing 20 per cent excess pressure as the allowable maximum.

For operations (5) and (7), the pressures required have been reduced somewhat because the requirements for truck wheels are not as exacting as for driving wheels and the

greater pressures approach too closely to the point at which the smaller diameter axles may bend. The reason for this reduction is readily apparent when it is considered that the relative stiffness of axles is expressed in terms of the cube of the diameter and the table of pressures is made in terms of the first power of the diameter.

In the table covering truck wheel mounting pressures, it will be noted that the figures followed by an asterisk are the Master Mechanics and Master Car Builders' Standards of 1916 as are also the preferred pressures used for cast iron and cast steel wheelcenters. For operations (2) and (4) covering cast steel driving wheel centers, having wheel fits, or crank pin fits 6½ in. in diameter or over, the preferred mounting pressures have been increased to 16 tons per inch of diameter with a minimum of 10 per cent less and a maximum allowable excess of 25 per cent above the preferred pressure. These increased pressures have been adopted for steel centers on account of the different characteristics of the material; *i. e.*, a somewhat lower coefficient of friction and a greater uniformity in the strength of the metal to resist fracture.

For operations (2) and (4) with wheel fits and crank pin fits under 6½ in. in diameter, the preferred mounting pressures are 13 tons per inch of diameter, and for the very small sizes, which are never used in ordinary locomotive practice, 11 tons per inch of diameter. For operations (6) and (8) the mounting pressures have been reduced for the same reasons as outlined for operations (5) and (7).

It will be noted that the mounting pressures for cast steel or wrought steel truck wheel centers, and cast steel or rolled steel trucks wheels, also agree with the Master Mechanics and Master Car Builders Standards of 1916. Locomotive trailing truck wheels over 36 in. in diameter are placed in the same classification as driving wheels in determining the mounting pressure. Crank pins and wheels applied at the pressures given in this table have given uniformly satisfactory service for a long period of years.

TABLE OF MOUNTING PRESSURES USED BY THE AMERICAN LOCOMOTIVE COMPANY

Seat diam. in in.	MOUNTING PRESSURES IN TONS										
	Axles and crank pins in: Driving wheels, trailing wheels (over 36 in. in diam.)						Axles in: Engine truck wheels, trailing truck wheels (36 in. in diam. and under), tender truck wheels				
	Cast steel centers			Cast iron centers			Cast steel or wrought steel centers.		Cast iron centers.		
	Min.	Prefd.	Max.	Min.	Prefd.	Max.	3.78 1/2 dollars for seat diam.	Min.	Max.	22.3 £. Cast iron chilled tread

EUROPEAN EQUIPMENT.—According to the British Ministry of Transport, 6 per cent of the cars are out of service awaiting repairs. The percentages of some other countries are: France, 15; Italy, 18; and Austria, 35. The percentage of locomotives awaiting repairs is 21 in Great Britain; in France, 22; Italy, 27; and Austria, 37.—*The Engineer.*

RAILWAY SHOP CONDITIONS IN ENGLAND

High Cost of Labor and Decreased Output Is Building up Excessive Costs—Great Need for Improved Devices and Modern Machinery

By ROBERT E. THAYER

European Editor of the Railway Mechanical Engineer

AS A DIRECT HERITAGE of the war England has had, in common with almost every other nation, to face a very great increase in the cost of labor. Wages have not only increased but output has been decreased through the adoption of the eight-hour day and a general decline in the morale of the workmen. The English railways and particularly the railway shops have felt these changed conditions keenly, more keenly perhaps than any other industry and surely more keenly than the railway shops of America on account of the fact that before the war English railways never had much worry over the cost nor the quantity or quality of labor.

With plenty of cheap and well trained workmen before the war, there was not the incentive for English railroad shop managements to adopt more modern systems of shop operation or improved shop appliances and labor saving machinery that existed in America where wages were high and skilled workmen were scarce. Furthermore, with cheap, well skilled labor and more or less unrestricted finances there has been every incentive for the railway mechanical officers in Great Britain to produce equipment that from the view point of workmanship was a work of art. Under the present conditions, however, this perfection in construction involves a high manufacturing cost that is being felt. In addition to this there has not been the demand for improved and new shop equipment to handle new equipment of increased weight and dimensions as in America, on account of the fact that the physical characteristics of the English roads, such as structural clearances and permissible weight on rail, have not permitted these roads to extend to the same extent as in the States. The equipment of 30 or 40 years ago is now not out of place on English roads. As a matter of fact there is still in operation much of the equipment built at that time. The English railway mechanical officer has therefore devoted the greater part of his time and energy on refinements in construction and design rather than on the increased size of his equipment or improved shop equipment.

The situation as it exists today presents an entirely different story. Labor is no longer cheap; output has been curtailed; materials have increased in price, and heavy deficits in net revenue present a demand for economy. The cost of maintenance and renewals of English rolling stock (including locomotives) has increased from £13,257,617 in 1913, to £14,156,816 for the first six months of 1919, or an increase of 213 per cent. The cost of locomotive running expenses has increased from £17,130,661 in 1913, to £18,168,295 for the first six months of 1919, or an increase of 212 per cent. If the railways of Great Britain are to meet expenses they either must increase their rates or operate more economically. There are great opportunities for savings to be made in the mechanical departments but investment will be necessary in shop equipment, and new and improved methods both in design, construction and repairing equipment will be necessary.

Locomotive building practices in Great Britain involve the

use of more expensive materials and a higher grade of workmanship than is demanded in the United States. The English locomotives have copper fireboxes, copper dry pipe and copper stay bolts, (about 2½ tons). In numerous instances these engines will be provided with copper tubes although with the present high cost of copper, steel tubes are more generally used. In addition to this many roads have a standard practice of using bronze driving boxes (about 550 lb. each) instead of cast steel driving boxes with the crown brass as is common in the States. This greatly increases the overhead cost of the locomotive and adds a greater carrying charge which naturally affects the net returns, particularly with copper at £105 and bronze at £180 per ton. There are but few locomotives that are provided with wedges in the pedestals, the designer preferring to provide an accurate sliding fit between the driving box and the pedestals in preference to bothering with shoes and wedges. This requires expensive fitting. The motion work in a number of cases is fitted on a testing table before it is placed on the locomotive. One road follows the practice of fitting its cylinders, crosshead guides, guide yoke, etc., on a dummy engine frame in order to ensure proper alinement, before they are placed on the locomotive.

The boiler practice is also carried to a higher degree of refinement than is used in the States. Many roads have what is called a parallel boiler, that is the different courses are butt riveted with a welt strip shrunk on. The barrel sheets are not laid out for the rivet holes on the flat but are assembled and each rivet hole is drilled in a huge ma-

Butt riveted boilers, concave journals and bronze driving boxes are some of the unusual features of construction found on British locomotives.

chine called a boiler barrel drilling machine. Most English roads use inside cylinders with cranked axles of both the solid and built-up type. Furthermore it is not uncommon to find the rear driving axles with concave journals and driving boxes fitted to these journals although it should be said that no new engines are built in this manner. It is a standard practice in flue works on some roads to stretch the flues after they have been removed from the boiler under repair to make up for the length cut off in removing the flues. In some cases tubes are stretched nine inches. This applies to both copper and steel tubes. In other shops safe ends are brazed on to the tubes, the safe end being milled and the tube taper-turned for fitting and a joint made with a copper ferrule. All spring work is done by hand, the methods of the past being perpetuated.

The railway shops themselves in many cases are old, representing a gradual development only in size. Railway shop practice, due as mentioned above to the fact that the cost of labor was so cheap before the war, has not progressed. Where American roads are now endeavoring to get away from as much fitting and bench work as possible, not only due to its excessive cost but on account of the fact that it is difficult to obtain first class machinists for this work, one finds in the English railway shop a large area of the shop space given over to this bench work.

It is all of these things which contribute to the excessive

cost of locomotive construction and repairs and it is here than the greatest field for economy is presented. The Railway Gazette, one of our London contemporaries, recently commented on the bids offered by British and American locomotive manufacturers on an order for the Egyptian State Railways. These figures show that the British builders quoted a price from 76 to 81 per cent higher than the successful American bidder. This will illustrate how the new conditions in the labor and material markets have affected British practices and give an indication of the necessity for more up-to-date shops in Great Britain.

The English roads generally build their own power and the British locomotive manufacturers deal more particularly with export business. As a result of this the English railroad will have under the jurisdiction of its mechanical department a more or less complete locomotive manufacturing plant. Taking one case in particular, that of the Crewe shops of the London & North Western, it might be stated that that plant needs only a coal mine and an iron mine located on its premises to make it self-supporting. The spreading out of locomotive building plants in this manner has also tended to increase the cost of locomotive manufacture, particularly on account of the fact that most of these plants are badly equipped.

As regards car building a similar policy is followed, that is, very few roads go outside for their new freight or passenger cars. A fine passenger car is built by the English railroads which in common with locomotives involves much labor. In contrast to this, however, are the freight cars which are nothing more or less than ordinary wagons mounted on axles and provided with an ordinary lever hand brake. The general size of these wagons is either of 10 or 12-ton capacity. They are simplicity itself in construction and due to the large number required to handle the business make a profitable manufacturing proposition for the individual railroads. But a very small number of these wagons are equipped with automatic brakes. They are principally of wooden construction, although due to the high price of timber a number of steel underframe cars are being built. The wheels are of a built-up design made in the car manufacturing plants. The shop cost for a pair of 38-in. wheels mounted on an axle having 9-in. by 4-in. journals is approximately \$125. The English roads have considered the use of cast-iron wheels but not having been sufficiently impressed with their safety, they still adhere to their own design of built-up wheel. The cost of these freight cars has increased greatly. Before the war a 12-ton open top car could be built by the railways for about \$400, but the present cost has been recently quoted as about \$1,000 in railway shops and about \$1,500 in car building plants. The car shops are more or less in the same category as the locomotive shops. There are some well laid out and well equipped shops on certain roads. Perhaps that of the Midland at Derby is the best in England. This shop contains many modern and improved woodworking tools, most of which were obtained from America.

This brief review of railway shop conditions in England indicates a wonderful possibility for improved railway shop appliances and machinery. Something must be done to reduce the excessive cost of manufacture and repairs, and with labor and material conditions so vitally different from what they were before the war, the railway shop managements are seeking a way out of the difficulty. It may be argued that with the English railroads in the hands of the government and with a standard net return guaranteed the shareholders, the English railroads will not be as anxious to make immediate improvements to their plants which would involve heavy expenditures. Government control will not run much more than 18 months hence and at the end of that time if the roads go back to their private owners economies must be anticipated to the greatest possible extent. On the other

hand, if the government retains control of the roads either through nationalization or otherwise there will still be the necessity for improvements. It is not believed, however, that the railways will defer taking action in such matters until they pass out of the hands of the government and in fact serious thought is being given to the modernization of railway shops by many of the more important of the British railroads.

LOCOMOTIVE TIRE HEATER

BY A. G. JOHNSON
Mechanical Engineer, Duluth & Iron Range

When the railway shops were required to use crude oil or kerosene in place of gasoline in tire heaters considerable difficulty was experienced. Many experiments were made and a number of different designs worked out more or less satisfactorily, but at times there was trouble in getting the heaters to start promptly. Time and oil were wasted and sometimes the shop was filled with gas and smoke from the oil, which, together with the flames, was not only annoying but dangerous.

To overcome these difficulties the tire heater illustrated was designed by N. Carlson, pit foreman of the Duluth &

Tire Heater Which Vaporizes the Oil Before Burning

Iron Range at Two Harbors, Minn. The heater consists of a piece of $\frac{1}{2}$ -in. iron pipe, bent in a continuous double helical coil, with spacing blocks to keep the pipes in the right position and the right distance from the tire. It is important that the latter distance so adjusted that the hottest point of the flame is at the tire. The first section of the coil has no small holes in it and merely acts as the pre-heater. The second section, which goes next to the tire flange, is provided with a continuous row of $\frac{1}{16}$ -in. holes, drilled $2\frac{1}{2}$ in. apart. The usual form of oil container and vaporizer is then connected to the shop air line and to the tire heater by a hose connection.

This form of tire heater has proved to be both easy to start and economical in the use of oil. It is possible to obtain a good blue flame with kerosene, and by making coils of suitable diameters any size of tire can be heated in a satisfactory manner.

HOW JIM DUGAN FINALLY WON A "REAL" JOB

Everything Went Wrong at Crossover Until He Took a Fresh Hold. First Entry in the Prize Story Contest

BY ANDREW J. FENTON

DRESSED in hip rubber boots, heavy mackinaw, an ear-lap cap pulled down over his ears and with thick gloves on his hands in addition to his regular clothing, Jim Dugan started through the deep snow for the roundhouse at Crossover.

He was tired, lame and stiff. It was near midnight when he quit work the previous night, and now he was leaving his home at six-thirty in the morning to get back on the job, for he knew from past experience that this heavy snow would put Crossover terminal out of commission unless he got on the job early.

It was a dog's life—work, eat and sleep. What pleasure did he get out of life anyway?

Stepping on a slippery piece of ice concealed by the snow, he slipped and fell, wrenching his back in his efforts to save himself from falling. Then the pop valve blew off, for what he said is not printable. Picking himself up and wiping the snow from his face, he continued on his way in a frame of mind that spelled disaster to any one who crossed his path that day.

Going to the ash pit first, he found it plugged—tied up tight with a long string of dead engines. It took some time to straighten out this tangle before he reached the roundhouse. There, too, he found a general tie-up.

Crossover only had a 24-stall roundhouse, and it required mighty close figuring to keep business moving. It was the terminal of three important busy divisions, and the company had for years talked about erecting larger and more modern terminal facilities, but so far they had managed to worry along with conditions as they were, although far inadequate to handle the business even under normal conditions.

For nine years Jim Dugan had been general foreman at Crossover, and during that time he had become so familiar with conditions that he was able to quickly straighten out any congestion within the scope of human intelligence. He had made a reputation in handling Crossover.

It was nearly noon before he reached his office, and by this time he was dead tired. Hurriedly glancing over the accumulation of messages and correspondence, he came to one letter which made him sit up and whistle. It was a circular letter sent out from headquarters and announced that Mr. Joseph Harris had been appointed general master mechanic of numbers one, two and three divisions. Yes, the three divisions of which Crossover was the all-important apex. And Joe Harris, his old side partner, too.

His first thought was that Joe Harris was a lucky man. Then, as he again read the letter announcing the appointment, his mind wandered back to the time, 20 years ago, when he and Joe Harris started to work as apprentice boys. They both began their apprenticeships on the same day and in the same shop.

Later as mechanics they worked in the same gang, side by side. Then he had been appointed gang leader and had drifted away from Joe. Shortly after that Joe Harris had quit the road and gone to another railroad. Then they had lost sight of each other entirely. In the meantime he had stayed with the company and had been promoted from gang leader to foreman, and then to roundhouse foreman, and later to general foreman at Crossover, where he had now been for the past nine years. To be sure, he had received no sensational promotions, but he had slowly climbed the ladder of success, and if there was to be a new general mas-

ter mechanic the job belonged to him by rights. He was the oldest employee and he had demonstrated his ability and loyalty on the road, so why did the company pass him by?

These thoughts filled his mind with resentment and anger. It was a fine way to show appreciation of meritorious service, holding a man down all his life, just because he could handle a terminal that no one else could handle. Several times in the years gone by there had been promotions made which rightfully belonged to him, but the officials had smoothed the matter over by either raising his salary or else bluffing him into believing that no one else could handle Crossover as he could and that he was such a valuable man at the terminal they could not move him without sacrificing the best interests of the company.

Brooding over these incidents, in addition to this last

What He Said Is Not Printable

insult, Jim Dugan made up his mind that he would quit right now before he was too old to secure a job elsewhere. Picking up a message blank he started to write out his resignation when the clerk poked his head in the office door and informed him they had just backed an engine into the turn-table pit.

Instantly Jim forgot all about his resignation, for he must get into immediate action. With the turn-table blocked his office was no place for him to be in. He must get on the job and get busy. Giving instructions to his clerk to call the wrecking crew, he rushed out to the turn-table.

By the time he again had things moving it was mid-

afternoon. He went to his office for a little rest and, stretching out in his office chair, he prepared to take a little nap. His office was hot, close and the air stuffy, hence in a few minutes he was sound asleep.

Suddenly he was awakened by his clerk, who told him that the superintendent of motive power had just gotten off No. 4 at the depot and was headed for the roundhouse.

Picking up his gloves, he saw his partly written out resignation. What an opportunity. Now he would tell the S. M. P. right to his face that he was quitting. He would not send a message, for that would be too brief. He had a lot of things he wanted to get "off his chest," and now was the chance.

Going out through the house he met the S. M. P., and they began to talk over several routine matters. At last

They Had Just Backed An Engine Into the Turntable

they reached the office, where it was quiet, and then Jim opened up. Somehow he couldn't say the nasty things he had in his mind, but simply told the S. M. P. that he was disgusted and was going to quit.

The S. M. P. showed his surprise at what Jim was saying and finally stopped him.

"Look here," he said, "you have never showed us that you were worthy of promotion. You have been here so long that you are in a rut. What we want in a man is progress."

"Does not nine years' successful service show some progress?" asked Jim.

"In a way it does. Just stop a minute and look at yourself. You have been here nine years. During that time you have kept things moving. But they were moving before you came here. You haven't done anything out of the ordinary. If we made you general master mechanic you would take the job just as it is and you would carry it along just as it is. We need action. We need a man who can see ahead and who can do things that will cause some notice. You are a follower—we want a leader," replied the S. M. P.

"But how can I show that I am a leader, buried here in this out-of-the-way place?" asked Jim.

"There you go. That's just the answer to why you are here. You cannot see—you want some one to point the way. When I got off the train this afternoon I knew you would have business going here at Crossover. Some other fellow would be tied up tight, perhaps. In other words, he would have done something to cause notice. Of course, if always bad, we would fire him, but if something of a complimentary nature, in time we would have to promote him. Crossover moves every day the same, nothing new or startling, and you move with it—neither up nor down. Show us that you

can get out of the rut and I will be the first man to shove you ahead."

There was no answer to this argument. Jim Dugan could see how true it was. He had buried himself; for nine years he had been his own worst enemy. When first he had taken hold of Crossover he had made a few half-hearted attempts to introduce new ideas, but as he had had no support from headquarters he had given up and slipped back into a rut, until now he was standing still. He would get support now.

"I will not resign, but from today on I shall act as if I had just been appointed to my present position. You are to know me not as Jim Dugan of the past nine years but as Jim Dugan with a future before him," said Jim.

"Let's shake on that," was all the S. M. P. could answer.

Jim Dugan faced a task. Many times during the next few weeks he was at the point of giving up, but he would grit his teeth and mutter, "I'll show him."

And as he progressed he began to feel ashamed of himself. Jim Dugan saw many of the little things which had escaped his notice in the past and which now loomed up big before him, as standing in the way towards successful management. He gave up taking his mid-afternoon nap—

"The S. M. P. Just Got Off No. 4"

one of the bad habits into which he had fallen. He spent less time in the road foreman's office visiting with engineers. He dug into engine failures personally. In the past his clerk had conducted such inquiries, but now he did the work. Much to his surprise, he learned a lot. He found conditions that should be corrected. He saw opportunities for new designs of equipment that would better the power. All these and many other recommendations he sent in to the head office, where they were simply acknowledged, but no action taken on them as far as he could see. But he did not

become discouraged—he kept plugging. He had made many changes at Crossover. His costs were decreasing, his men were satisfied—he was now making a record.

He heard that a certain type of engine was giving all sorts of trouble on one of the other divisions. He asked to have them assigned to his division so that he could study them. Soon he located the trouble, corrected it, and the engines were a success.

Many nights when he went home he was dead tired, but in the morning he was always anxious to get back on the job, for there was some question that always needed his personal attention. Where life had been a drudgery it was now a pleasure. He looked for engine failures with joy, for it would give him a chance to check up and conquer. But engine failures had stopped, so he turned to other things. He tidied up the place, he painted, he did a thousand and one things to place Crossover on the map—and he succeeded.

One day he received a message; "Report to headquarters

tomorrow a. m.," was all it said. He wondered what it was; nothing to fear anyway.

When he reached the S. M. P.'s office he met the general manager, who greeted him with, "Hello, Jim, how does it seem to have a real job now?"

Bewildered, Jim looked to the S. M. P. for an answer. "Oh! yes, Jim, I forgot to tell you, that you are general master mechanic of numbers, one, two and three divisions," said the S. M. P. in answer to Jim's look.

"Well, I don't know whether or not I want to leave Crossover," replied Jim turning and looking at the general manager.

"Ain't that hell," said that worthy official, "it's hard to get a good man and we certainly need a man like Dugan for general master mechanic."

"Dugan will take the job, I know, for that's a little understanding we have between ourselves," said the S. M. P. as he slyly winked at Jim.

HEAT TREATMENT OF STEEL IN THE TOOL ROOM

Equipment and Methods for Tempering Carbon and High Speed Steel, Hardness Tests and Service Records

BY M. H. WILLIAMS

THE art and methods of hardening and tempering tools, such as are made in railway tool rooms have received a great amount of attention in the last few years, and as a result there has been a decided improvement in the wearing and lasting qualities of these tools. In many cases, in order to bring about this desired result it has been necessary to change practically the entire method of handling the work.

Not many years ago it was the custom for the blacksmith to harden and temper all tools, the heat being governed almost entirely by observing the color of the tool, both when hardening and when drawing the temper. These men became very expert at their work and produced results that at the time were considered satisfactory. As the art of steel making advanced and methods of testing tools were introduced, it was found that by the older methods, even with the most expert workmen, the wearing qualities of tools did not equal the results obtainable or demanded.

The present good results may be attributed principally to the gradual improvement in furnace design, devices for recording or measuring the heat, instruments that will measure the hardness of the tool after tempering, and last but not least, the records that are made of tools when hardened, the latter giving a brief history of the kind of steel, heat treatment, hardness, etc. In the event that a tool does not stand up properly the records may be consulted and the next lot modified in the treatment to overcome the defects. These records are also valuable when a new design of tool is to be hardened, as by consulting them, data concerning tools of similar nature may be considered and the treatment arranged accordingly.

TEMPERING SHOULD BE DONE IN THE TOOL ROOM

The question of the location of furnaces for tool hardening has been the subject of considerable study. In the past it was the custom to do practically all tool hardening in the blacksmith shop, often in open forge fires. This has proved bad practice when compared with more modern methods, later investigation having shown that it is advisable to locate furnaces for this work in the tool room. In this location the work will be under the eye of the tool room foreman,

which makes him responsible for the entire manufacture. This location in turn brings up the question of men for the work. On account of the different natures of tool hardening and ordinary blacksmith work it is difficult to find much similarity in two crafts. Generally there will be found enough tool hardening in railway tool rooms to justify the employment of a man for this work only, who can make a study of hardening and tempering and devote his entire time to it. This employee may have been employed at hardening by the older methods. If such a man is not available, a man entirely new at the work may be employed, who should work according to rules laid down by the foreman, who in turn may obtain practically any information desired concerning the average hardening and tempering of tools from catalogues of steel manufacturing companies, text books, or the greatest educators of all in this line, the very efficient agents who travel for the steel companies and who are always ready to give instructions as to hardening, and also to do the actual hardening and tempering for demonstration purposes. Here the value of records comes in. When an expert hardens a tool a complete record should be made at once, so that when it is necessary to harden a similar tool, all the data will be available.

To those who have not made a trial of the scheme of employing men who are not experts at this work it may appear dangerous. However, with present day methods, it is the custom of several tool-making concerns to instruct the hardener as to the time the tool should remain in the furnace, the temperature to maintain, the quenching temperature, the quenching liquid, time and temperature for drawing the temper, etc. The data for issuing these instructions is taken from card records of similar tools hardened or the sources of information mentioned above.

HARDENING FURNACES

It goes without saying that good furnaces that may be maintained at a uniform temperature are necessary if satisfactory results are to be obtained. At the present day a furnace that cannot be maintained within 10 deg. of the desired temperature cannot be considered satisfactory, and with a number of

the later designs this is obtained without any great amount of care on the part of the operator. Several makes of combined pyrometers and heat regulators are now on the market for automatically controlling the supply of gas or electricity used by the furnaces. By the use of these devices, temperatures are maintained as desired, with but little attention on the part of the operator. Where additional furnace equipment is contemplated for use with gas fuel or electricity these regulating devices should be carefully considered.

For all around tool room furnace hardening natural or city gas appears to meet the requirements better than other fuels. With properly constructed furnaces and a good supply of gas, the heat may be controlled to a nicety, and it is unnecessary to erect a stack except in very badly ventilated rooms. In some locations gas is not available, making it necessary to use fuel oil, coke or the more desirable method, electricity.

A furnace for tool room hardening, making use of any fuel, should be so constructed that the direct flame does not come in contact with the article to be hardened. This desirable condition may be accomplished by making use of a combustion chamber in which the gas and air, or oil and air, after leaving the burner and before entering the heating chamber thoroughly combine and form a hot gas, which in turn enters the heating chamber. The result, if a well designed combustion chamber is provided, will be that in the heating chamber there will not be any appearance of a flame, but simply an intense red heat surrounding the article to be hardened equally on all sides, resulting in an even heat, which is very essential. Furnaces in which the flame is visible cannot be considered satisfactory, and they should be rebuilt or renewed.

One of the very satisfactory forms of gas furnaces is constructed so that the gas and air combine in the combustion

Fig. 1. Cross Section of a Typical Gas Furnace

chamber below the hearth as shown in Fig. 1, in which *AA* are the walls lined with firebrick, *B* the hearth supported from the bottom of the furnace on piers of fire brick, *CC* the burners, and *D* a vent at the top. With this furnace the gas and air after combining at the burner, enter the lower chamber *E*. This gas mixture passes up between the hearth *B* and the walls of the furnace and into the heating chamber *F*. As a result the article to be hardened does not come in contact with the direct flame. The pyrometer when used in this furnace generally enters through a hole in the rear wall. In order to properly equalize the heat it is customary to locate burners on each side.

In many cases gas furnaces not equipped with combustion chambers may be rebuilt to obtain the benefit of the lower combustion chamber by building a hearth of firebrick resting on piers of like material. Several good makes of gas furnaces are now on the market that may be purchased at reason-

able prices, and it will often be found more economical to order one of these than to attempt to rebuild present equipment.

OIL FURNACES

Many railway shops are located where gas is not available. It then becomes a question of making use of fuel oil, kerosene, coke or electricity, electricity being without a doubt the best suited for the purpose. However, in cases where this can not be obtained at reasonable rates, it is often necessary to resort to other fuels.

A number of designs of oil-fired furnaces are employed. One very satisfactory type, known as the oven-fired, is shown in Fig. 2. This design has a combustion chamber *A*, heating chamber *B*, a perforated arch *C*, a hearth *D*, set above a waste heat duct *E*, and the customary roof *G*. The burner *F* is placed at the side. The walls *HH* are supported on suitable legs or built up solid from the floor. The leg construction is more desirable for small sizes generally used in tool

Fig. 2. Oil Furnace of the Over-fired Type

rooms. As ordinarily constructed, the hearth is supported from the floor of the furnace by fire brick pillars, the duct underneath connecting with the vent duct shown. Also an opening is made from the heating chamber into the duct *E*. The arch *C* is made of perforated firebrick such as is supplied by makers of this material. The oil burner and the necessary air connections are generally inclined slightly so as to direct the flame above the arch *C*. The direction of the flame is indicated by arrows. In the combustion chamber the air and oil after leaving the burner combine and form a hot gas that passes downward through the perforated arch and into the heating chamber in which the articles to be hardened are placed, the waste heat from the heating chamber passing through the duct *E*, which also heats the hearth, and up through the side vent. A furnace of this nature is often used without a vent to the roof in well-ventilated rooms. The pyrometer, as in the case of the gas furnace, is passed through an opening in the back wall. This form of furnace may be maintained at a fairly uniform heat, provided the supply of oil and air is regular, and will, as a general rule, be found as satisfactory an oil furnace as any design made. The consumption of oil may be somewhat greater than other forms. However, the consumption of fuel for tool hardening is always secondary to satisfactory results.

ELECTRIC FURNACES

There are a number of types of electric furnaces that are giving most excellent results for tool room hardening. In fact, the results are so very good that their installation should be carefully considered in any railway tool room where the

proper current is available. One very satisfactory type is the Hoskins, shown in Fig. 3. This is made up of a heating chamber *A*, at the top of which is placed a carbon connecting plate *B*. Two piles of thin carbon plates *DD* form the sides. These rest on graphite bottom plates *EE*, which in turn rest on the adjustable electrodes *FF*, which are controlled by the adjusting screws *GG*. These electrodes *FF* are kept cool by water circulating through the clamps *HH* and pipe *I*. The bottom of the furnace or hearth is made up of some insulating material, such as cement. The electrodes *FF* are surrounded at the lower end by asbestos packing, and at the top by sand, in order to form an air-tight seal and allow for the movement of the electrodes. All these elements are sur-

Fig. 3. Carbon Plate Electric Furnace

rounded by a heavy wall made up of heat-resisting material, and as a result very little heat escapes to the room.

This furnace works on the electric resistance principle. That is, a poor passage for the electric current is purposely provided, which results in heating these conductors. Or to make use of a comparison, it is on the same general principle as the electric heater used in electric street cars or the electric flat iron. In this case the carbon plates *DD* at the sides of the furnace offer considerable resistance to the passage of the current, and as a result they are heated according to the amount of current passing and the resistance they offer, this heat being radiated into the heat chamber. The passage of the current is as follows: Starting at the right hand side, the current from a transformer is connected to the clamp *H*; it then passes through the electrode *F* to plate *E*, to carbon pile *D*, to top plate *B*, and over and down to the left hand clamp *H*, in a similar manner, and to transformer.

By varying the pressure applied to the adjusting screws *GG*, the resistance to the passage of the electric current through the carbon plates *D* may be varied, which in turn governs the amount of heat transmitted to the heating chamber. The furnace takes its current from a special transformer wound for low voltage and high current. This, however, may be connected to the regular alternating current shop lighting or power circuits. It can not be used on direct current circuits. When starting, the current is switched on and pressure on the screws *GG* adjusted to obtain the correct flow of current. When the proper heat is once obtained very little adjusting is required to maintain a uniform heat. A

pyrometer is used to indicate the heat of the heating chamber, similar to the practice with oil or gas furnaces. With this furnace there is but a very small amount of oxidizing or scaling of the work, owing to the fact that the air does not enter the heating chamber. It is suitable for either carbon or high speed steel, and on account of the small amount of heat radiated from the walls, may be located in tool rooms in close proximity to other tools or workmen. It has the advantage that a chimney is not necessary.

ELECTRIC BATH FURNACE

Another design of electric furnace that has been used to a limited extent in railway tool rooms makes use of a salt bath. In this type of furnace certain grades of salts are melted by the passage of the electric current through them. The articles to be hardened are immersed in the salts similar to practices with lead furnaces. Fig. 4 shows one form of electric bath furnace. This is made up of a crucible *A*, generally of fire clay or similar heat-resisting material that is a non-conductor of the current, on two sides of which are placed electrodes *BB*. A hood with a vent to the roof is necessary to carry away the gases and fumes, which are injurious to the operators. In practice, the crucible is filled with some form of salt, such as sodium nitrate and sodium chloride for the lower temperatures, and a mixture of potassium chloride and barium chloride for temperatures generally used when hardening carbon steel, or barium chloride only for high speed steel, the proportions of these mixtures being varied to suit the conditions and temperatures required. The

Fig. 4 . Electric Bath Furnace

proportions of each are given in instructions furnished by makers of the furnace.

These salts when cold are non-conductors of electricity, but when hot, readily conduct the current. In starting, it is customary to connect a piece of electric arc lamp carbon to one of the electrodes by a wire and strike an arc in the salt near to the opposite electrode. As the salts melt, the carbon is gradually drawn away from the electrode. This forms a canal of melted salt, which conducts the current. With the current once started across, the entire mass soon becomes liquid. It is customary to keep the furnace hot at all times, which is accomplished by allowing a small amount of current to flow during the night or when not in service. The electrodes *BB* are made from pure wrought iron and are led in over the top of the crucible and down into the salt bath. These are connected to the secondary of a special

transformer, that is arranged with suitable taps and switches so that the required amount of current may be obtained, the current being shown by an ammeter. The temperature of the bath is ascertained by a pyrometer, the fire end of which is placed in the salt bath.

The work to be hardened is hung on wires and immersed in the bath and rapidly takes the same temperature. After immersing a sufficient length of time to insure complete penetration the work is withdrawn and quenched in the usual manner. Or in case of special intricate pieces they are allowed to preheat on a shelf above the bath before being placed in the solution.

This form of furnace is especially useful for carbon steel and has several good points, of which the following may be mentioned. On account of the exclusion of air from the piece while it is immersed in the bath there is no oxidation, and when it is removed from the bath a thin film of salt adheres to the surface. As a result, pieces hardened show no signs of scale. This is very desirable, for taps, dies, gages and special tools. On account of the large mass of heated salts, the furnace does not cool down to any great extent when work is placed in it. For carbon steel it gives most excellent results and is to be highly recommended. For high speed steel it is necessary to renew the electrodes at frequent intervals, and it becomes a question of whether this furnace is a paying proposition. Before installing, it is advisable to look into the question, as the art of heating by electricity is advancing so fast that it is dangerous to say one day what will be done in the next.

This furnace, like the one previously explained, gives out very little external heat, and can therefore be placed in tool rooms. On account of the fumes, a chimney must be provided.

BATH FURNACES OR LEAD BATHS

Certain long articles which are made in railway tool rooms, such as stay-bolt taps, taper frame bolt reamers, etc., cannot

Fig. 5. Lead Bath for Heating Tools

well be hardened in the customary tool-hardening furnaces without constructing them too large for the average demands. Also, on account of their comparatively great length, it is difficult to obtain a uniform heat over the entire tool in the average furnace. To overcome this difficulty the lead bath or salt bath is employed. As a general proposition, of the two methods the lead bath appears to meet the requirements better, all things being considered.

One form of this furnace is shown in Fig. 5, where A is the pot, which for use with lead is generally made of cast iron or seamless steel tubing closed and welded at the lower end and flanged at the top to rest on the brick casing. The

seamless tubing construction is much preferred on account of its longer life. The circular brick work BB forms the wall of the furnace, and is lined with firebrick, the diameter of the inside being sufficient to allow the flame to readily pass around the pot. A burner C, that may be used with gas or oil, is provided, that directs the flame below the pot. A hood D for carrying away the fumes given off by the lead is quite necessary on account of the poisonous nature of these fumes, although by keeping the top of the lead covered with powdered charcoal the fumes are very much reduced. A pyrometer is generally placed in a vertical position in the pot, care being taken not to allow it to touch the pot.

In practice the pot is filled with lead or some suitable salt, such as a mixture of barium chloride and potassium chloride, and heated to the required temperature as indicated by the pyrometer. Articles to be hardened are immersed in the bath and allowed to remain until heated to the same temperature as the bath, when they are withdrawn and quenched in the customary manner.

There is always the possibility where lead is used of small particles of lead adhering to the surfaces, which interferes with the proper hardening of some tools, such as stay-bolt taps, by reason of the cooling medium, such as water or brine, not reaching the steel, resulting in soft spots. To guard against this several methods are employed, one being to paint the article with a mixture of common whiting and wood alcohol, or whiting and water. If the latter is used it is necessary to dry the piece thoroughly, otherwise the lead will fly and may injure the operator. With the salt bath this is not necessary.

There are a number of advantages to be gained by the use of the lead bath furnaces as compared with ordinary gas or oil-fired furnaces. On account of the entire absence of air surrounding the tool while hardening there is no scaling. This is very essential for taps. On account of the large volume of lead the temperature can be maintained within close ranges and is very little affected when placing cold pieces in the bath. In addition to taps these furnaces are used quite extensively for hardening drills, reamers, flue tools, chisels, etc. For articles like chisels and rail cutters, where it is desirable to heat only a part of a tool, the lead bath gives most excellent results, and is so much superior to the ordinary open fire as to warrant its installation for this purpose only. Therefore, it may be said that no railway tool room is complete without the lead or salt pot furnace.

SCALING OF TOOLS DURING HARDENING

Scaling or oxidation of tools during the hardening process is objectionable, especially where they are of a nature not admitting of grinding after hardening, such as taps, gages, etc. This scaling follows as a result of air or oxygen entering the heat chamber and being absorbed by the steel while at the higher temperatures. With practically all forms of furnaces, with the possible exception of the salt or lead bath, a certain amount of scaling is bound to take place while the tools are in the furnace and during the short interval between removing from the furnace and quenching. Proper regulation of the air used with gas or fuel oil will have the effect of reducing the amount of scale. In order to approach the desired results it is necessary to obtain as nearly perfect combustion as possible before the flame enters the heating chamber. This is accomplished to a greater or less degree by proper regulation of the flow of air along with the fuel used. This makes a uniform pressure of air very essential. The use of air from the average blacksmith shop blower line is objectionable on account of variations in pressure, resulting from the intermittent use of forge fires. High pressure air, such as is used for air hammers and similar tools is also not to be recommended on account of uneven pressure and from the cost standpoint. Where this

must be used the conditions may be improved by the use of suitable reducing valves between the shop line and the burners which, let us say, will reduce the pressure down to 20 lb. This will give a uniform pressure at the needle valve of the burner even if the shop line pressure varies.

Where possible, a separate fan should be installed for tool room furnaces. In order to obtain proper combustion with gas or oil a pressure of about 10 ounces should be available. This is generally greater than the average blacksmith shop line. Where fuel oil is used it is also necessary to obtain a uniform pressure in order to feed the burners at a uniform rate. This may be accomplished in most cases by erecting a stand pipe or tank near the furnaces.

Furnaces for this work should be kept as tight, as possible both in the walls and doors. Special care should be given the latter, as in the event of air entering, the scaling will be increased. One very good scheme to insure a tight door is to build the door side of the furnace on a slight incline, say about 10 deg., and hang the door to slide against this surface. With proper hanging for the door it can be so arranged that when down it will make a very good surface contact with the furnace, and when lifted will draw away from the wall. With this form there is no need for guides for the door, on account of the door only resting against the furnace. In the event of an explosion or puff of fire the door is blown outward without other damage. It is now customary to provide all furnace doors with self-closing peep holes. By opening these the temperature of the articles in the furnace may be judged by comparing the color with the pyrometer fire end. That is, when the tool and the fire end are one color both are at one temperature, a slight variation being quite noticeable when looking at both at one time. However, the fact that the tool on the outside is of the proper temperature does not indicate the time to quench, for in order to insure proper hardening the tool must remain in the furnace long enough after the outside is of the proper temperature to insure complete and uniform penetration of the heat all the way through.

FURNACES FOR TEMPERING OR DRAWING BACK

The oil bath and electric furnace, or electric oven as it is more properly called, are now largely used for drawing the temper of tools. By the use of either, very satisfactory

Fig. 6. Oil Pot for Drawing Temper

results are obtained, this method being very much superior to drawing the temper by observing the color of the tool.

The oil bath form shown in Fig. 6 is made up of a cast or wrought iron pot resting on a circular brick or cast iron wall or stove. Underneath the pot the necessary burners are placed for use with oil or gas, according to the fuel available. The pot is filled with a special grade of high fire test oil sold for this purpose by concerns making a specialty of these oils. The pot is provided with a hinged cover arranged so that it may be closed instantly in the event of the

oil firing, when the closing of the cover smothers the flame. A glass bulb thermometer is generally suspended in the oil for the purpose of indicating the temperature. As it is often the practice to draw the temper of a large batch of tools at one time a chain block is often placed above the furnace for the purpose of lifting the baskets in which the tools are held out of the pot.

In practice several pieces of a similar nature which may be the result of a day's hardening are placed in the perforated basket and lowered into the oil bath, preferably when the oil is at a low temperature, say below 200 deg. F. The oil is then gradually brought up to the required temperature and held at this temperature from one to three hours in order to insure that all pieces assume one temperature and that the heat penetrates all the way through. The basket is then withdrawn and the work allowed to cool in the air. Placing the tools in the oil when it is comparatively cool eliminates the possibility of setting up local strains in the previously hardened tools and reduces the breakages as compared with placing the hardened tools in a furnace that is at a high temperature.

ELECTRIC DRAWBACK FURNACES

This form of furnace is now used quite extensively for temper drawing. Generally they are made up of a heating chamber very similar to regular hardening furnaces, the chamber being enclosed by firebrick or heat insulating material. The door is generally hinged on one side and made to fit very closely into the opening, being locked in a manner similar to the practice with stoves. The heating units, which are made up of electrical resistance wire, are placed at the sides of the heating chamber. The passage of the current through these units causes them to give off heat that in turn heats the oven. The heat is controlled by suitable rheostats or switches, and in some cases a thermostat is arranged to automatically control the heat to whatever degree it may be set. When the furnace comes up to the desired heat some of the heat units are cut out or resistance is added, which automatically controls the temperature to the required degree without hand control. In practice the work is placed in the oven and the temperature gradually brought up to the required heat and held there for the correct amount of time.

This form of furnace has several good points, of which may be mentioned the almost entire absence of heat in the room, a uniform temperature under good control, absence of smoke or smell, safety, and when provided with a thermostat, a uniform heat is obtained without hand regulation.

These oil bath and electric drawback furnaces have many advantages compared with the older methods. On account of the slow rate of heating there is not the danger of causing a fracture in the steel, and the heat penetrates to the center and insures uniformity throughout the piece. This is of particular value when drawing the temper of a piece of irregular shape or section. The method is much cheaper, as a large number of pieces may be drawn at one time without more attention than watching to insure the correct temperature. There is also a considerable saving on account of avoiding the necessity for brightening the work.

The temperatures agreeing with the various colors generally used for drawing back are as follows:

	Deg. F.	Deg. C.
Very pale yellow.....	430	221
Light yellow.....	440	227
Pale straw yellow.....	450	232
Straw yellow.....	460	238
Deep straw yellow.....	470	243
Dark yellow.....	480	249
Yellow brown.....	490	254
Brown yellow.....	500	260
Spotted red brown.....	510	266
Brown purple.....	520	271
Light purple.....	530	277
Full purple.....	540	282
Dark purple.....	550	288
Full blue.....	560	293
Dark blue.....	570	299

This table will serve to connect the various colors and temperatures. However, on account of the fact that heating in an oil bath or an electric oven is quite a different operation from drawing by colors, a certain amount of experimenting is often necessary in order to determine the correct temperature and time the tools should remain in the drawing furnace. When this information has once been obtained the results may be duplicated with great accuracy, and if shown on card records it should not be difficult for a person not familiar with hardening to obtain satisfactory results. This is much to be preferred to relying on some one man for this work.

PYROMETERS

The great advances in the art of hardening and heat treating of steel that have been made may be attributed very largely to the pyrometer. In fact, it would at the present time be almost impossible to get along without this valuable instrument. Any tool hardening plant without these is very much out of date.

Pyrometers are so universally used that a lengthy description cannot be considered necessary. The principal part of this outfit is the indicator, which is constructed as far as the working part is concerned very similar to volt meters, practically the only change being the size of wire used and the graduation of the dial, which is graduated for degrees Fahrenheit or Centigrade instead of volts or amperes. The thermocouple, or fire end, is generally made up of two wires, each of a different composition, the two being welded together at one end and connected at opposite ends to wires leading to the indicator. The wires making up the fire end are enclosed in a metal or porcelain protecting tube to prevent the direct heat coming in contact with the wires. When the joined ends of the fire end are heated a very feeble current of electricity is generated, which is indicated by the needle of the indicator. The scale of the indicator is graduated by the makers to read in degrees of heat according to the heat at the fire end. These fire ends, on account of continued heating, will wear out, for which reason it is customary to purchase several with each instrument. They are now made of two classes, one being known as base metal, made from steel wire or alloys, which are suitable for temperatures up to about 1,700 deg. F., and used very largely when hardening carbon tool steel or casehardening. These are not expensive. For higher temperatures, such as are necessary for high speed steel that may go as high as 2,400 deg. F., it is necessary to employ fire ends made from platinum and platinum-rhodium or similar metals. These are very expensive and can only be recommended where it is necessary to harden expensive high speed tools.

Pyrometers, like any delicate instruments, are liable to get out of order if abused or not given proper attention. It is customary to encase the indicator in a protecting case to exclude dust, and it should be mounted on a firm wall or support. This part of the pyrometer outfit is so well made that trouble rarely occurs. The thermocouple, or fire end, when made of any metal is liable to errors, and must be frequently calibrated in order to insure accuracy. The question of calibration will be considered later.

A pyrometer can be installed by the regular shop electrician who follows the instructions given with the instrument. The indicator should be located out of range of the direct heat of the furnace. The wires are generally run in conduit similar to lighting circuits. The fire ends are generally passed through the back wall of the furnace, a hole being made for that purpose. The fire end should not be removed except when making calibrations. Good practice generally indicates that a separate indicator should be used with each furnace, in which event they are banked on a suitable board secured to the wall of the building. By

this method the temperature of all furnaces is under the eye of the hardener at all times.

For certain classes of service recording pyrometers are used. These make a record of the temperature very similar to the records of air and steam pressure in power plants. It is a question whether these are necessary in tool rooms where this work is under the eye of an expert.

There are a few points in connection with the use of pyrometers that should be carefully observed, one of these being the case of the hot and cold ends of the couple. The amount of current generated and the movement of the dial needle depend on the difference in temperature of the hot end, which is placed in the furnace, and the cold end, which is the opposite end of the couple. Generally these couples and dials are graduated to read correctly when the temperature of the cold end is at the average room temperature, or about 70 deg. F. If the cold end is too close to the furnace and its temperature is raised, the readings will be affected accordingly. That is, if instead of 70 deg. it is 100 deg., the readings will be 30 deg. low.

In order to overcome this difficulty it is now found to be good practice to run the wire connecting direct to the fire ends downward to the floor, on account of this location being little affected by heat from the furnace. One method followed with good results is to use wires from the outer end of the fire end to the floor, made of the same metal as the fire ends and join the copper wire to them in a junction box located at the floor, this junction box being similar to that used for electric wiring. This results in making a very long fire end where the cold end may be kept away from the heat of the furnace. Where this practice is followed great care is taken to secure good joints between the wires of the fire ends and the extensions.

Another method followed is to run the wires of the fire end, after leaving the furnace, in conduit, and surround this conduit by a second pipe, through which a stream of water flows which keeps a uniform temperature at the cold end.

It may now be well to consider what is to be gained by the use of pyrometers as compared with the older method of judging the heat by the eye. Books issued by known standard authorities on the subject of tool steel all call attention to the importance of correct temperatures when hardening and tempering tools. The more careful steel making concerns employ chemists and test department experts who make a business of testing tool steel in order to ascertain the correct temperature when hardening, in order to obtain the greatest strength, wearing qualities or resistance to shock and also grade the steel according to the use intended. The information obtained by these concerns is generally shown in their catalogues or can be obtained by letter, the most approved methods of treatment being set forth. This information will show that practically every different tool requires a different treatment and grade of steel in order to obtain the best results.

Steels that are similar in general make-up and trade name, but differ in carbon content, must be treated differently. The higher the carbon the lower the heat required. To take an actual case of one grade of tool steel. If .100 carbon it should be hardened or quenched from 1,350 deg. F. The same grade of steel but with .060 carbon should be quenched from 1,400 deg. F. This may not appear to be a very great difference. However, quenching only a few degrees from the correct temperatures will affect the wearing qualities of the tool and may result in one tool of a batch standing up well and another made at the same time from the same bar failing.

Generally speaking, in order to obtain the best results carbon tool steel should be quenched just after reaching the so-called decalescence point, which is a heat where the steel changes its nature. Or, in other words, the steel has

changed, and by quenching is held in this changed state. One peculiar property of steel is that at the decalescence point it becomes non-magnetic. Going to a higher heat will not improve conditions or make the steel enough harder to be of value. In fact, the results will be the reverse, as a higher heat will result in a coarse grained steel, which is always an indication of poor steel or treatment. Again, practically all tools must have the temper drawn after hardening. This being the case, nothing is to be gained by overheating the tool when hardening and drawing back this extra hardness in the tempering operation. Reasoning will indicate that the tool should only be heated just hot enough to harden it properly. In order to determine the proper heat it is necessary to be governed by reliable pyrometers.

For the purpose of ascertaining the drawback or tempering heat where furnaces are heated by a flame the regular pyrometer may be used. This method of procedure is but little followed at the present time.

For the electric oven and oil bath drawing, the glass bulb thermometer is now largely used. These are of special construction for the purpose, and are enclosed in a suitable protecting casing to prevent injury in case the articles being drawn strike the casing. These thermometers are made with a scale reading high enough for all ordinary drawback temperatures.

When used in an oil bath the bulb is immersed in the oil, or when used in an oven an opening is made in the wall through which the thermometer passes. These thermometers are generally very reliable and have the advantage that they will not change with age. However, even with the greatest care the glass will at times break, therefore it is always advisable to have an extra one on hand.

A study of the table of temperatures and corresponding colors that has been given will show the small difference in temperature between colors used when following the old method of tempering and will also serve to illustrate the necessity for accurate temperature readings and maintaining the oil bath and the oven at the proper temperature.

TESTING AND CHECKING PYROMETERS

A pyrometer to be of value must be properly calibrated and kept in order and a number of methods are followed for this checking. One way is to compare the work instruments with a standard instrument kept for checking purposes only. In this event the standard instrument is generally of the portable kind that may be carried where required. When used, the fire end of the standard instrument is placed in the furnace close to the work fire end, and when the two are of the same color, as may readily be detected by the eye, i. e., the same heat, the check and work pyrometer readings are compared. If they do not agree the work instrument is tagged, showing the amount high or low. The hardener then makes allowances to compensate for this error. In case the fault is in the indicator, this part may be repaired by the maker, or if an expert on this work is available adjustment may be made locally. This work, however, can only be done by an expert. Where a number of pyrometers are used about a shop a high class standard check pyrometer will be found to be a good investment.

Where the shop is not large enough to warrant a standard check pyrometer other means of checking are followed, one method being to compare the pyrometer with the thermometer used in the oil bath. This is done by immersing the fire end in the oil bath alongside of the thermometer and comparing readings. This will check up to the limit of the heat of the oil, which is rarely over 650 deg. F. This method is fairly accurate, as the glass thermometers are generally correct within a small error. It has the disadvantage that the pyrometer is not tested at the average working temperature for carbon steel, which is generally between 1,350 and

1,450 deg. F., and if the indicator is in error the chances are that the reading will not be correct at the higher readings. However, one of the principal causes of error is the gradual wearing away of the fire ends, owing to heating and cooling, and as a test of this nature will show these errors, and can be made very quickly, it is recommended as a frequent check.

Certain minerals and salts are known to have a clearly defined freezing point, or, in other words, the point where it hardens, just as water freezes at 32 deg. F. One of the most reliable substances is salt, which freezes at 1,472 deg. F. This temperature is close to the average hardening point of carbon steel, and is therefore often used. A very satisfactory method of testing the accuracy of a pyrometer with salt is as follows: For the purpose of melting the salt a graphite crucible should be used when it can be had. Suitable tongs or bale should be provided for lifting it in and out of the fire. As a makeshift a sort of deep frying pan may be used that can be made from steel as follows: A four-inch bar of steel five inches long is drilled about four inches deep with a three-inch hole, a handle being welded to it. These pots are then filled with salt and placed in a furnace or forge fire and heated until the salt melts. The fire end is then placed in the melted salt and allowed to remain there while over the fire until the salt and fire end are of the same color and heat. This may take several minutes, the fire end being connected to the indicator while this is going on. The pot and fire end are now removed from the furnace and allowed to cool. As the salt cools readings should be taken each 10 seconds, or, better still, a curve made on cross-section paper, the temperature being set down on horizontal lines and the time on the vertical lines. When the salt freezes the needle of the pyrometer will remain stationary for a few seconds, this freezing point being clearly defined and can be detected very readily. After a few seconds the needle will again go backwards. The pot should then be placed in the fire and heated to remove the fire end, after which the salt should be washed off as it is injurious.

It is important that the cold end of the fire end be kept at the room temperature while this test is being made. If the pyrometer reading differs from 1,472 deg. F., the instrument is tagged accordingly. It is necessary to obtain pure salt for the purpose of making this test. Generally the common grade known as table salt will be found reliable. However, where there is a laboratory in connection with the shops it is advisable to obtain salt of known purity from that department. In any event, the salt must be kept clean and free from other impurities which will affect its freezing point.

QUENCHING TANKS

In order to properly harden the great variety of tools such as must be made in these tool rooms several quenching tanks are necessary, all of which must be of ample size in order to guard against a too rapid heating of the quenching solution and to maintain a uniform temperature of the liquid. Unless this solution is maintained at the correct temperature the variations will have a marked effect on the hardening. Generally speaking, tanks 36-in. by 36-in. by 36-in. of $\frac{1}{4}$ -in. material, preferably with seams welded, meet the requirements in a very satisfactory manner. These should be provided with hinged covers that may be closed when the tanks are not required, in order to keep out dirt and foreign matter.

The following quenching mediums are recommended: clear water, salt water or brine, and oil. For the larger rooms it is advisable to install two tanks for each of these solutions in order to be able to alternate from one to the other as the solution becomes warm. In many cases cold water or steam pipes, or both, are placed in these tanks for the purpose of maintaining a uniform temperature. By

making proper use of the water or steam the liquid can generally be kept near a uniform temperature. As an illustration of the value of this, suppose it is necessary to harden a large batch of tools at one time similar to flue tools. If proper provision is not made to maintain a uniform temperature of the water or oil used the first of the tools quenched in the colder solution will be the harder, and while this may not be a very serious question, it is desirable to harden all tools of a batch alike, and as this can be accomplished readily by the use of proper cooling coils it certainly is worth while making provision for them. For some classes of hardening, especially nickel steel, it is often necessary to warm the water to possibly 200 deg. F. in order to prevent too rapid cooling. The same holds good where it is necessary to harden a piece of irregular section or where there are a number of sharp corners where warming the solution will prevent cracking the piece quenched.

The location of tanks with reference to the furnaces is also important. Where possible it is advisable to place these all in a row facing the furnaces with a space of some six feet between.

When hardening articles having concave surfaces similar to drop forging dies, or hollow articles such as hollow mills used on screw machines, it is advisable to equip one tank with a nozzle or spout which may be made of gas pipe loose jointed to enable the stream to be changed to meet different conditions. When hardening, the stream can be directed on the surface requiring the hardest surface to insure proper results.

In addition to the quenching tanks an air blast for high speed steel hardening should be provided. The mistake should not be made of using compressed air from the shop line without a reducing valve to cut down the pressure.

THE SCLEROSCOPE

No tool room can be considered complete without a scleroscope, this being an instrument for measuring the hardness of metals. It was the custom at one time to test all tools after hardening with a file. This was a rough and ready method that would tell when a tool was too soft but would not indicate when it was too hard or how much too hard or too soft. By the use of the scleroscope the exact hardness of any tool may be measured with great accuracy. This makes it possible to test the hardness of tools, and in case they are not correct, to modify the method of hardening and tempering.

This instrument works on the principle that if a weight that has been very carefully made as regards size, weight and shape of point be dropped from a uniform height the rebound of the weight when striking any substance will be governed by the hardness of the substance hit. This can best be illustrated by a homely comparison of dropping a marble. Suppose a marble is dropped on a wooden floor. The rebound will be a certain amount. If the same marble be dropped from the same elevation on a concrete floor the rebound will naturally be much greater on account of the increased hardness of the concrete as compared with the wood floor. This same principle is used in the scleroscope, which is so constructed that the weight will always be dropped from a certain predetermined height. By observing the height of the rebound on the scale the actual hardness of the metal is determined.

This instrument, which is shown in Fig. 7, has a glass tube *A*, with a scale graduated to 140 equal divisions much like a thermometer. Inside this glass tube is placed a small weight having a sharp-pointed diamond set in the bottom, this weight being free to move inside of the glass tube. For the purpose of raising the weight the soft rubber bulb *B* is squeezed and then released. The vacuum above the weight lifts it to the top of the tube, where it is caught by

a catch in the round cage at the top of the instrument. When the bulb is pressed the second time the weight is released and falls, striking the object to be tested, and then rebounds, the amount of rebound being noted on the scale, which may be easily read. This rebound may indicate 40 for soft steel, 60 to 70 for the ordinary chisels and flue tools or possibly as much as 100 for extra hard tools. A magnifying glass, as shown, is employed, which assists when making close readings.

The instrument is leveled by leveling screws *E* and may be raised or lowered by turning the knurled nut *F*. The rod *D* acts as a plumb hob to show when the glass tube is perpendicular. Small articles are placed on the platform *G*. The glass tube is then lowered by means of the nut *F* until

Fig. 7. The Scleroscope

the metal at the end of the glass tube rests on the piece to be measured. The weight is then raised, allowed to drop, and the amount of rebound measured.

When it is necessary to test articles that are too large to go on the platform the instrument is held in a swinging bracket and located above the point where the tests are to be made. In this event, it is customary to hold the article in a vise or rest it on the work bench or an anvil.

The graduations on the glass tube have no particular meaning. However, they are similar on every instrument made. Therefore, readings made from any instrument will be alike when measuring the same hardness of steel. This makes it possible for one shop or the engineering department to instruct other shops having similar instruments as to the hardness of tools and also to compare results from time to time.

This instrument should be used for testing the hardness of each tool made in the tool room. The result will be that tools not properly hardened will not get into service. A record should also be made of each tool or batch of tools. From this the tool room foreman can tell just how hard a tool was made. If it has stood up well the hardness may be set as a standard and future tools hardened and drawn to

the same degree. If a tool when in service was found too hard or too soft the next ones made can be varied to meet requirements, the records being consulted to find the hardness of the defective tools. As an illustration, take the case of a flue beading tool. This should not be too soft or the throat will batter up; or too hard, as it will break. The scleroscope will measure this hardness, which for this tool should be between 60 and 70, as shown on the scale. Cutting tools, such as drills and taps, are generally harder and may show 80 to 90. This instrument is very valuable for high speed tools, as an expensive high speed tool, such as a milling cutter, drill or reamer, may be readily broken if too hard. The mistake is often made of not properly drawing the temper of these tools under the impression that high speed steel must be very hard. The scleroscope will detect where these tools are too hard and often prevent costly breakages.

In many shops it is the practice to test each tool made with this instrument in order to pick out tools that may not have been properly hardened and which is also a check on the entire operation of hardening, tempering and grade of steel. To make this test it is customary to grind a smooth surface on the tool, which may be done on a wheel or by hand, and make the test on this ground surface, the actual preparations and testing only requiring a few seconds. The knowledge that all tools leaving the shop are correct and detecting and rehardening the defective parts very much overbalances the cost of making the tests.

RECORDS OF HEAT TREATMENT

A card record of tools made in tool rooms will be found of great value. On these cards may be recorded the more important points concerning the various tools manufactured, such as the name of tool, blue print number, maker and grade of steel, temperature to which heated when hardening and time in furnace, quenching medium, whether tool was cooled in clear water, brine, oil, etc., drawback temperature and time in furnace or oil bath, scleroscope hardness and, last but not least, space should be provided in which to record the general behavior of the tools, a sample form of card being shown in Table I.

TABLE I. TYPICAL FORM OF TOOL RECORD

(Over)	

Where a record of this nature is kept it may be consulted to show the entire history of the tool. As an illustration, take the case of staybolt taps. A lot made may wear too rapidly when in service. The card index covering the taps in question may be consulted and the probable cause of the defect determined. This may show a scleroscope hardness below 65, indicating that too high a heat was used when drawing the temper or other causes. If some of the lot of these taps are on hand that have not been used, they may be rehardened and drawn to the correct degree of hardness. If, after the second treatment, the taps hold up in a satisfactory manner it will be an indication that the correct hardness has been arrived at, which would then be a subject of record.

A record made of tools purchased, such as the name, date,

maker, hardness, etc., that stand up well in service, is also of value for consultation when making similar tools. Take the case of the staybolt tap. If necessary to make these in an emergency or to recut them to a smaller size, the record of satisfactory taps will at once indicate the proper degree of hardness.

One class of tool largely used is the bridge reamer, required for steel car repairs. In order to properly stand up these must be of the proper hardness. If too hard excessive breakages will result, or if too soft rapid wear will follow. By recording the hardness of a number of these and noting results, a standard of hardness may be arrived at. Or if these are purchased it will be found advisable to test for hardness before placing them in use, and record the results. In the event that they have not the proper hardness the matter can be taken up with the manufacturers. During times of close competition it is advisable to let the manufacturers of tools know that the grade of tools is being watched, both for the good of the railway shop and also for the manufacturer, as the latter will generally welcome any criticism that may lead to the betterment of his product. Where it is possible to go back to the manufacturers with a statement of facts that satisfactory tools average, say, 70 on scleroscope reading and that the defective parts showed only 60, the statement will carry weight.

For ordinary tools, such as chisels, rail cutters, etc., the record of hardening and scleroscope is of value and well worth keeping. For the less frequently made tools, such as milling cutters, the records are of especial value. Where these tools have once been made and the data recorded, it is always possible to consult the record when a new tool of a similar nature is to be made. The previous method can then be followed if the tools were satisfactory, or modified in order to overcome any error. This record is of particular value for high speed steel cutters and various other tools made from this material on account of the high cost of the steel, and guards against the mistake often made of allowing too hard tools to go into service.

COMPRESSOR LIFTING CHAIN

BY A. G. JOHNSON
Mechanical Engineer, Duluth & Iron Range

In removing and applying the Westinghouse 8 1/2-in. cross-compound air compressor, the chain shown in the illustration

Chain Sling and Method of Attachment

will be found very convenient. The chain is made of 1/2-in. stock of the strength indicated, the ring at the top being made

of $\frac{3}{4}$ -in. stock. In operation the chain is slipped over the top of the compressor around the valve chamber, as shown. The hook from the crane or chain block is then hooked into the large link, and when tightened up the chain is drawn around the valve chamber in such a way that it cannot slip. The compressor balances nicely, and it is comparatively easy to adjust the compressor so that the bracket bolts can be readily applied.

BALL JOINT VISE FOR DIE SINKING

Few railroad shops possess special die sinking equipment, and for that reason the vise shown in the accompanying drawing will be found especially useful. The adjustable jaws have a range to $9\frac{7}{8}$ in. The ball can be swung through an angle of 45 deg. in any direction and is clamped

The Committee on Standards, after carefully investigating the use of autogenous welding in connection with the construction and repair of locomotive boilers and fireboxes, has, in the interest of safety and efficiency, adopted the following rules:

1. Autogenous welding will not be permitted on any part of a locomotive boiler that is wholly in tension under working conditions; this to include arch or water bar tubes.
2. Staybolt or crown stay heads must not be built up or welded to the sheet.
3. Holes larger than $1\frac{1}{2}$ in. in diameter when entirely closed by autogenous welding must have the welding properly stayed.
4. In new construction, welded seams in crown sheets will not be used where full size sheets are obtainable. This is not intended to prevent welding the crown sheet to other

A Vise Which is Adjustable to Any Angle

by tightening the bolts holding the upper ring. The hand work involved in making dies can often be greatly reduced by the use of this vise, as the parts can be securely held at the proper angle to permit as many operations as possible to be performed on machines.

RULES FOR AUTOGENOUS WELDING

The following rules adopted by the Committee on Standards for the purpose of preventing the use of autogenous welding for purposes for which it is not well adapted, have been sent to the regional directors by Frank McManamy, assistant director of the Division of Operation, with instructions to direct all roads to observe the rules in the construction or repair of locomotive boilers, so that any failures which may have been caused or contributed to by unrestricted or improper use of autogenous welding may be prevented.

firebox sheets. Side sheet seams shall not be less than 12 in. below the highest point of the crown.

5. Only operators known to be competent will be assigned to firebox welding.
6. Where autogenous welding is done, the parts to be welded must be thoroughly cleaned and kept clean during the progress of the work.
7. When repairing fireboxes, a number of small adjacent patches will not be applied, but the defective part of the sheet will be cut out and repaired with one patch.
8. The autogenous welding of defective main air reservoirs is not permitted.
9. Welding rods must conform to the specifications issued by the Inspection and Test Section of the United States Railroad Administration for the various kinds of work for which they are prescribed, which specifications will be issued later.

NEW DEVICES

MORRIS RADIAL DRILL

A well proportioned radial drilling machine which up to its capacity is capable of pulling high speed drills at their maximum speed, has been placed on the market by the Morris Machine Tool Company, Cincinnati, Ohio. This machine is of rugged design, easy to operate, due to conveniently located control levers and can be used to good advantage in drilling, tapping, facing and counterboring operations.

The column construction does not vary greatly from standard

General View of Morris Radial Drill

practice, except that being supported on both a large ball bearing and a roller bearing, the arm can swing with exceptional ease. Suitable arrangements are made to rigidly clamp the column in the stump. The arm sliding on the column has a long bearing and can be clamped in any position by one lever, conveniently located. The arm can be raised and lowered by power through the lever at the top of the column. This lever has a tendency to throw itself into neutral when the tumbler gears are engaged, thus making it necessary for the operator to keep his hand on it when raising or lowering the arm. The tumbler gears are idle except when forced into mesh by the lever. The base, which is exceptionally deep and well ribbed, is provided with the usual T-slots and oil channel. The oil reservoir has an overflow partition to keep chips and dirt out of the pump.

The illustrations show a general view of the drill and a rear view of the head, which is heavily constructed. The head, being carefully balanced on the ways of the arm, travels

freely and an extra wide tapered gib is provided to take up the wear. The clamping arrangement consists of two screws operated by one handle against the gib. The angle of the teeth of the helical spindle gears shown is great enough to insure more than one tooth meshing at a time, which avoids end thrust and eliminates the slight chatter usual with spur gears. The use of helical gears also insures a quiet, strong drive. A graduated dial depth gage, which trips the spindle speed at the desired depth, is another valuable feature of this new radial drill.

The back gears, mounted in a fully enclosed bracket, directly in back of the head, are made of $3\frac{1}{2}$ per cent nickel steel, heat treated and hardened. Through these gears two speeds are obtained by a lever on the left hand side of the head. The reversing gears and friction clutches are mounted

Rear View of Head Showing Heavy Construction

in the same bracket, fully enclosed and running in oil. The lever controlling the reversing or tapping attachment is at the lower right hand side of the head, within easy reach of the operator.

The drill spindle is a hammered forging of high carbon steel, ground true to size and the end thrust is taken care of

by a ball thrust bearing. Four feeds are obtained and marked on a dial in thousandths advance per revolution of the spindle. The feed can be automatically tripped at any depth within the traverse of the spindle. All the spur gears are hobbled and the bevel gears are carefully generated on a gear shaper.

The speed box is mounted on the base of the machine and six speeds are secured by means of the vertical lever on the front of the box and the friction lever on top. The latter controls the double friction clutch on the pulley shaft and when in neutral position stops every revolving part except the pulley shaft. All friction clutches in the feed box and the tapping attachment are of the expanding ring type. The rings are ground in an expanded position, thus insuring true contact when thrown in. They are of large diameter and wide face and are capable of a pulling power considerably greater than the capacity of the machine. The bearings throughout are made of bronze, arranged with oil chambers, the oil being drawn into the bearings by felt wipers. Arrangement is made for constant speed motor drive with the gear box, or variable speed motor drive through one pair of gears to the lower shaft. In the latter case a four-to-one variable speed motor would be necessary.

This radial drill is made in three sizes, 2½ ft., 3 ft., and 3½ ft. The maximum distance between the spindle and the base is 52¾ in., and between the spindle and the table is 31¾ in. The spindle traverse is 12 in., and spindle speeds vary from 20 to 400. A 3-hp. motor is required to drive the machine.

STEEL SUPPORTS FOR ELEVATING TRUCK PLATFORMS

The introduction of elevating trucks, now extensively employed around shops and storehouses, necessitates the use of special types of truck platforms. These have usually been made of wood and considerable trouble has been experienced, especially where heavy loads are handled, owing to the fact that the skid on which the platform is mounted frequently breaks, causing trouble in operation aside from the expense of repairs. To obviate this difficulty, the Lyon Metallic

Steel Supported Truck Platform Loaded with Tin Plates to Capacity Greater than the Truck Can Lift to Show the Strength of Construction

Manufacturing Company, Aurora, Ill., has devised a steel skid leg. It consists of two welded feet which are in turn welded to a steel channel, this channel being provided with bolt holes spaced at suitable distances to provide for bolting on either a wooden or steel top. The skid legs can be used for platforms of any width depending on the length of the cross pieces. Another advantage of this device is that additional platforms may be carried in stock, knocked down,

so that they take up very little space and yet are available when needed. The illustration shows a platform constructed with these skids, carrying a lead of seven tons. This is a greater weight than could be carried on the elevating truck but shows the great strength obtained with this method of construction.

EMERGENCY CONNECTIONS FOR BRAKE PIPES

The attention of railroad men and supply manufacturers is constantly being given to improvement in the installation and repair of train pipes, with the result that many useful devices have been developed. One of these devices which has proved very efficient is shown in the illustrations. It is a method of coupling broken pipes which does away with the necessity of cutting threads that has been devised by J. L. Broschart and is now being manufactured by the Broschart

A Pipe Coupling Which Can Be Applied Without Tools

Threadless Pipe Coupling Company, Trenton, Mo. The object is to facilitate repairs in case of breakage of pipes forming part of the air brake or steam heating system either on locomotives or cars. In actual service as a part of the equipment carried on locomotives and cabooses, the threadless coupling has been found useful in preventing delays and engine failures, eliminating the necessity of switching cars to the rear of the train or cutting them out with the consequent expense of sending a mechanic to make repairs.

Method of Using the Emergency Connection in Making Temporary Repairs to Broken Brake Pipes

As shown in the illustration the coupling consists of a short section of pipe *A*, which carries two jam nuts *B*, and *D*, rubber gaskets *E*, and lock nuts *F*. In case a break occurs in the train line, the ends are separated about four inches enabling the coupling to be inserted in the pipe. By turning the jam nuts, the rubber gaskets are compressed and forced out against the walls of the pipe making an air tight connection. If the break occurs at the end of a pipe coupling or union, the tapered end of the jam nut is sufficiently long to allow the gasket to extend through into the pipe and make a tight joint. By the use of other fittings train lines can be connected even though the broken ends cannot be separated and in a similar manner angle cocks can be replaced and other air or steam pipes can be connected or plugged. The coupling can be applied without the use of any tools. It will withstand the standard trainline pressure and will not interfere with either service or emergency applications of the brakes.

HARTEND GENERAL SERVICE CAR, AND HART DOOR GEAR

There are in service a large number of gondola cars fitted with drop doors through which more or less of the load may be dumped when the cars are handling bulky products such as coal or road building material. To be of the greatest value when handling such commodities, the drop doors should occupy the maximum possible proportion of the floor area in order that the least amount of shoveling may be necessary to clear the car. Such cars have been built with doors occupying the entire length of the floor on both sides of the center sill. In such designs, however, it has been difficult to secure sufficient structural strength at the corners to prevent distortion of the frame from the use of the push pole, so that the doors bind and are not easily operated.

In a number of designs this difficulty has resulted in the exclusion of drop doors and the use of a solid floor between the bolsters and end sills. Another difficulty which has discouraged the use of doors beyond the bolsters is the fact

vides a rigid end construction, provides for the complete discharge of the load with practically no shoveling, and incidentally provides cubical capacity in the corner hoppers for from one and one-half to two tons additional load. A level floor is retained between the bolsters so that the suitability of the car for loading with lumber, rail, ties or other similar material is unaffected. As the hopper doors are readily operated directly by hand, this design permits the drop door shaft operating mechanism to be placed at the bolster where it is not exposed to damage from corner blows as it is when located at the ends of the car.

Another feature of recent development which is included in the construction of the car illustrated is a simple door locking and dumping mechanism, which may be applied to the drop doors of any general service gondola car of conventional design.

Generally speaking, door operating mechanism is more or less troublesome to maintain in satisfactory operating condition. Where chains are used to raise the doors they usually offer some obstruction to the movement of material in unloading and frequent readjustment is required to insure

Half Sections of the General Service Car Showing the Operation of the Hart Door Gear

that, with these doors included, the operating mechanism must be placed at the end sill of the car at each corner. Here it is usually unprotected from abuse which frequently renders the mechanism inoperative.

With these two objections to the usual design of completely self-dumping gondola cars in mind, the National Dump Car Company, Chicago, has developed a design of drop bottom gondola known as the Hartend general service car. The purpose of this design is to provide a stiff end construction incorporating a solid floor plate from the end sill to the bolster at each end of the car, but arranged in such a manner that the load in this part of the car may be dumped at the side, as it would be through a drop door. How this has been accomplished is indicated in the illustration showing the end elevation and interior of the car. Between the bolster and end sill at either end the floor plates are sloped downwardly and outwardly from the center sill, in effect forming a hopper at each corner of the car. The outer sides of these hoppers are closed by swinging doors hinged at the top and easily closed and locked by hand. This design pro-

vides uniformity in closing all of the doors operated by one shaft. In the Hart door gear no attempt has been made to provide for the closing of the doors by the operating mechanism and all chains or other flexible connections between the doors and the shaft have been eliminated. Each door is closed by hand and temporarily latched, after which each group of doors is permanently locked as a unit. In unloading, a half turn of the permanent locking shaft releases the whole group.

For closing the doors each is provided on its under side with a metal socket and fulcrum so arranged that when the end of a short lifting bar is inserted in the socket the bar is held in a position convenient for raising the door. Mounted in short slots formed near the outer ends of the cross members of the underframe is a rolling shaft. When the doors are opened this shaft is moved to the outer ends of the slots, close to the side of the car so that it clears the outer edges of the doors. With the shaft in this position, as each door is raised by means of the lifting bar, the operator moves out a simple sliding latch on the under side of the door so that

its outer end rests upon the shaft, thus temporarily securing the door in the closed position. When all of the doors in each group have thus been secured they are permanently locked in the closed position by rolling the shaft inward through one-half revolution. For this purpose an operating lever is permanently attached to each shaft. In locking the doors this lever is turned up against the side of the car and locked in position by a sliding link, which is dropped over its end. As the shaft travels inward it engages the downwardly projecting lug or handle on the temporary latch and moves the latch back so that in dumping it offers no obstruction to the dropping of the door.

The drop doors are divided into two groups on each side of the car with the operating lever on each locking shaft located at the bolster end of the shaft. To dump all of the doors in each group the link is raised off the end of the

The Hartend Car Showing the Side Hoppers at the Ends

shaft operating lever, which is then turned outward and downward through approximately one-half revolution, thus rolling the shaft out from under the doors and allowing them to drop by gravity.

From an inspection of the drawings, it is evident that the rack on which the shaft is rolled is slightly elevated toward its inner end so that locking the shaft also tends to close the doors tightly against the bottom of the car. By closing each door individually any dirt or obstruction which might interfere with its proper closure is cleaned off so that the doors are easily closed and locked without being strained themselves or putting excessive strains on the locking mechanism.

Should they be warped or sprung, however, the slope of the rack on which the shaft rolls affords a range of about 1 in., within which a sprung door causes the operator no difficulty in the closing and locking operations.

A sample car incorporating the end hopper and the Hart door operating mechanism has been in service several months handling soft coal. In this service it has proved to be self-clearing and incidentally has demonstrated its advantage in many instances, where cars are being unloaded into wagons on a team track, of making it possible to dump a small portion of the load at one corner to afford a place for shoveling without dumping an entire quarter of the load, as is usually necessary.

ADJUSTABLE POINT CENTER

An adjustable point center for lathes and grinding machines with several important advantages is shown in the accompanying illustration. The inserted point, made of specially hardened high speed steel, is held in place by a locking screw and can be adjusted for wear by means of the central pin and adjusting screw indicated. The body of the device is made of carbon steel with a hardened surface to prevent mutilation and a soft core for greater strength.

It is claimed that the use of this center in either a lathe or grinder will result in considerable saving over the old style of solid center. The high speed steel point will not readily overheat or burn, and when it does require grinding can be removed easily without moving the tailstock. The time required for grinding also is reduced because of the shorter angle to be ground and heavier feeds which can be

Robinson Adjustable Point Lathe and Grinding Machine Center

used. The grinding time has been reduced from 15 to 2 or 3 minutes.

Another advantage of an adjustable point center is that no allowance need be made for wear in the body. Therefore, the work being turned is brought closer to the tailstock and spindle, which reduces the chatter and protects the machine from extra wear. As the point is gradually worn, it is adjusted with the regulating screw, and when finally worn out the point alone may be scrapped instead of the whole lathe center.

This adjustable center is made by the Robinson Adjustable Center Company, Detroit, Mich., and can be used in the spindle or tailstock of any of the standard lathes or grinding machines.

INCREASED WAGES CONSUMED 97 PER CENT OF INCREASED RATES.—Increases in freight and passenger rates made during federal control amounted to \$1,835,000,000 when applied to the traffic moved up to July 31, 1919, while the increases in wages applied to the number of employees and the hours or days worked in July, 1919, amounted to \$1,774,800,000, or 97 per cent of the revenue from the increased rates, according to a statement compiled by the Interstate Commerce Commission at the request of Senator E. D. Smith of South Carolina.

ADJUSTABLE WALL RADIAL DRILL

The field for the use of wall column radial drills has been materially extended by a power elevating device incorporated in the radial drill, illustrated in Fig. 1, developed

Fig. 1—Lynd-Farquhar Wall Column Radial Drill.

by the Lind-Farquhar Company, Boston, Mass. The power elevating mechanism increases the capacity, and makes the

Fig. 2—View Showing Rigidity of Construction.

machine adaptable to a greater range of drilling operations. A four-foot vertical adjustment of the arm on the column is provided for and controlled by means of a vertical controller

rod. An interfering device is provided which prevents the operator from raising or lowering the arm at high speeds, eliminating the chance of breakage from this cause. A friction coupling is also provided in the elevating mechanism, which will prevent breakage in case the operator neglects to lower the gib screws on the column.

The rigid construction of this wall radial drill is shown in Fig. 2, which also indicates the motor drive and vertical controlling levers. In addition to the vertical braces, 1-in. by 3-in. tie rods are used, and in this way a very rigid and substantial structure is secured.

Four changes of spindle speed are provided through an improved design of gear box with a single pulley drive, which readily lends itself to a compact arrangement for motor driving, with a silent chain and sprocket when desired. These four speeds are controlled by conveniently located levers within easy reach of the operator.

TIER-LIFT ELEVATING TRUCK

An industrial truck, which with its own power elevates the loads to sufficient heights to put the material in box cars or stock rooms without rehandling, has been developed by the Lakewood Engineering Company, Cleveland, Ohio. This new truck performs the functions of a tiering machine as well as those of a load-carrying storage battery truck, and is called the Tier-Lift truck. It can elevate a two-ton load to a maximum height of 76 in., or to any intermediate height.

It has always been customary to transport material by means of hand trucks or some kind of power-driven truck which acted as a carrier only, but with this method men are required to transfer and lift the loads, and even when cranes are available considerable manual labor is required to handle the material. The use of this Tier-Lift truck, however releases the cranes from considerable work, gives a more flexible distribution system and reduces the waste of man-power

Elevating Truck Placing a Load in a Box Car

The height to which material can be piled economically is greatly increased and the storage capacity of a given floor doubled or tripled by the high lifting feature. The storing of material on skids to prevent rehandling in the storeroom is also made practical. Where the material is such that it can bear the weight of loads above, the loaded platforms can be piled on top of each other. The labor cost is thus reduced, material can be handled more quickly and the storage capacity of the floor space is greatly increased. With the

arrangement shown any loaded platform in the racks may be removed without disturbing the other loads, thus giving flexibility in the storeroom.

It is claimed that the four-wheel steer allows the truck to turn in a circle 92 in. in radius, thus permitting operation in narrow aisles or congested parts of the plant, and giving easy entrance into box cars, small storerooms, etc. The same form of drive is used in this truck as in the Lakewood tractor. There are three speeds forward and three speeds reverse. The controller handle is conveniently located for operation for travel in either direction. The lifting mechanism is operated by means of a specially designed controller with one speed in either direction. The lifting is done through two steel worm screws, a separate motor being used to supply the power.

The load platform is carried by a cantilever type support and the load is balanced over the carrying wheels. Ball bearings are used throughout and by a special design the friction losses in elevating and lowering the load platform are greatly reduced. It is claimed that the truck is easy to operate, and its use will result in a considerable saving of both time and labor.

POWERFUL HIGH SPEED JACK

Several new features of construction are embodied in the latest design of high speed ball-bearing screw jack, built by the Duff Manufacturing Company, Pittsburgh, Pa. This 75-ton jack is particularly adapted for handling locomotives and other heavy railway equipment, because it is powerful, quick acting and can be moved easily. The distinguishing feature of this jack is the fact that the operating mechanism, instead of being located in the head, is placed in the

which operates a double-thread screw through a ratchet and gearing. The screw has a steep pitch, making the action exceptionally rapid for a jack of this capacity. The screw is made of special machinery steel, heat treated, and turns in a bronze nut of special composition. This combination of bronze and hard steel materially reduces friction.

Safety is assured by a positive clutch which holds the load at all times, preventing any possibility of its sinking or lowering. Another safety feature is the signal which is provided to indicate when the jack has reached its maximum height. For lowering the jack a crank handle is used and a few turns only are required, as the action is very rapid. Regardless of the speed with which the load may be descending, it may be safely checked at any point desired. The action is positive, so there is no possibility of the jack sticking during the lowering operation.

For the purpose of testing a Duff jack the rear end of an N-1-s type locomotive, weighing 215 tons, was raised, so that the rear wheels were off the track. It was estimated that the jack supported a weight of over 95 tons, showing that the 75-ton rating is conservative. This new type of high-speed ball-bearing screw jack is made in heights of 20, 24 and 26 in., capable of maximum lifts of 6, 10 and 12 in., respectively.

HEATING RIVETS ELECTRICALLY.—In a paper read before the American Electro-Chemical Society, Chicago, G. M. Clark states that two American concerns have developed methods of heating rivets electrically. The American Car and Foundry Company employs a method whereby the rivet itself forms a short-circuit connection across the secondary

Duff 75-ton Jack Is Easy to Move and Rapid in Action.

base. As shown in the illustration, the weight is thus concentrated at the bottom instead of the top and the jack is not top-heavy. Another advantage is that the point at which the operating lever is pivoted does not rise with the load, which allows a full, powerful stroke regardless of the height of the load.

The Duff jack is unusually easy to move about, not only because the concentration of weight in the base gives a low center of gravity, but because, by inserting the operating lever in a special socket, the jack can be tipped over by one man and rolled on its own wheels wherever needed. The load on the jack is raised by means of a six-foot steel lever

of a transformer. A spring device holds the rivet in the desired position across the ends of the transformer while the operator holds the rivet with a pair of tongs and brings the spring holding device into operation by means of a foot lever. The consumption of electrical energy is about 20 units per 100 lb. of rivets, and the time taken to heat the rivet naturally varies with the size of the rivet. In another type of heater, employed by the Electric Furnace Company, a granulated carbon block forms the short-circuiting device across the transformed secondary, and in turn radiates heat to the rivets. The consumption of electrical energy for this type is about 18 units per 100 lb. of rivets.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Subscriptions, including the eight daily editions of the *Railway Age*, published in June, in connection with the annual convention of the American Railroad Association. Section III—Mechanical, payable in advance and postage free: United States, Canada and Mexico, \$2.00 a year; Foreign Countries, \$3.00 a year; Single Copy, 20 cents.

WE GUARANTEE, that of this issue 12,200 copies were printed; that of these 12,200 copies 11,064 were mailed to regular paid subscribers, 20 were provided for counter and news company sales, 216 were mailed to advertisers, 32 were mailed to employees and correspondents, and 868 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 12,200, an average of 12,200 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. P. C.).

The Chicago, Milwaukee & St. Paul, aiming to reduce materially the losses on perishable foodstuffs, has created a new department, heated refrigerator service, in charge of O. M. Stevens. A new design of charcoal heater has been installed in 1,000 refrigerator cars in which are carried food products subject to injury by freezing.

It is reported that the Prussian Railway system is contemplating the use of internal combustion locomotives of the Diesel type to be used on proposed electrified lines, and it has already been decided that such locomotives will be built for experiment having a horsepower of 3,000. One of the purposes attributed to this work that in case of war these locomotives could be used over any tracks, even though electric power was not available.

A statement showing the number of women employed on railroads under federal control, received by the director general from the manager of the Woman's Service Section, shows that between April 1, 1919, and July 1, 1919, there was a decrease of 23.6 per cent in the number of women employed in roundhouse work, a decrease of 18.5 per cent in the number employed in shop work and a decrease of 15.1 per cent in the number employed in the car department.

The Philadelphia & Reading has received orders to turn over 14 of the 17 locomotives that had been built for the Russian government and which were stored at the roundhouse in Reading, to the Cumberland Valley Railroad. Thirty of these locomotives were originally received by the Philadelphia & Reading and were used on different parts of the system, but later a number were sent to the Reading shops, where they were stored after receiving a general overhauling.

Engineering Council has requested and the Director of the Census has ordered that the new census shall include a more detailed classification of engineers, so that technical engineers will be listed separately from non-technical engineers (stationary engineers, locomotive enginemen, etc.), enabling any one to ascertain readily the number of technical men in the United States and in each state. Technical engineers will be further subdivided between civil, mechanical, electrical and mining.

There is an unconfirmed report in Peking, China, that the Ministry of Communications has engaged the services of four

foreign experts to assist in the standardization of rolling stock. France, England, Japan and America are said to be represented upon this group. For two years or more a Railway Technics Commission, composed of Chinese, has been working upon this subject. It is reported that this commission will submit to a convention of the mechanical officers of the lines, to be called next spring, a set of standards for goods wagons.

The Southern Pacific (Lines North of Ashland) has been awarded a banner by R. H. Aishton, regional director of the Northwestern region, for obtaining the best results of those roads employing over 2,000 men in the Northwestern region during the recent National Railroad Accident Prevention Drive. Although employing 4,676 men and operating 1,222 miles of road, the Southern Pacific (Lines North of Ashland) had no reportable casualties to employees during the entire period of the drive, while during the same two weeks of 1918 one employee was killed and 13 were injured.

The railway brotherhoods and other labor organizations, having received no encouragement from the Railroad Administration on their latest requests for increased wages, are working on a plan for reducing the cost of living through their own efforts by co-operative buying, production and distribution. Announcement has been made in Washington of the formation of the All-American Farmer-Labor Co-operative Commission, of which the officers of the railway unions are the officers to carry out the plan, and B. M. Jewell has issued a statement indicating the conclusion that increases in wages will not solve the problem, because they result in a vicious circle of increasing prices. The plans are to be perfected at another conference in Chicago, February 12.

The Engineering Experiment Station, Urbana, Ill., will have eight vacancies to fill in the Research Graduate Assistantships at the close of the current academic year. These assistantships, for each of which there is an annual stipend of \$500 and freedom from all fees except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics, or applied chemistry. An appointment is made and must be accepted for two consecutive collegiate years, at the expiration of which period, if all requirements have been met, the

degree of Master of Science will be conferred. Not more than half of the time of a research graduate assistant is required in connection with the work of the department to which he is assigned, the remainder being available for graduate study. Additional information may be obtained by addressing The Director, Engineering Experiment Station, University of Illinois, Urbana, Ill.

The Tank Car Maintenance Problem

An article entitled The Tank Car Maintenance Problem, by Paul Bateman, appeared on page 647 of the November issue of the *Railway Mechanical Engineer*. This was an abstract of a paper presented before the Mid-Continent Section of the American Society of Mechanical Engineers and should have been credited to Mechanical Engineering.

American Firms Offer to Establish Belgian Car Works

According to a despatch from Brussels, copyright by the Chicago Tribune, the Belgian government has asked for offers for the building of railway rolling stock.

One offer has come from two American concerns, the despatch says, the Middletown Car Company and the American Car & Foundry Company, which combined efforts for the occasion. They offer to create on Belgian soil works for the construction of railway cars which would be installed on American lines. They would, however, employ exclusively Belgian labor; only the chiefs and engineers would be Americans.

After the delivery of the ordered carriages this model factory would be put, free of charge, at the disposal of the Belgian State. It would constitute ideal repair workshops with a staff of 2,500 men, which would have gone through a five months' "American training." The works would be connected by about eight miles of railroad.

The Middletown Car Company started in 1917 a model factory for the American army in France at La Rochelle which has an output capacity of 110 railway carriages a day. The parts for the cars would come from the United States and would be put together in the continental shops.

Commenting on the above despatch in New York, W. H. Woodin, president of the American Car & Foundry Company, said that such a plan had been considered while he was in Belgium recently, but the final action had not been taken.

Railroad Labor Leaders Object to Return of Roads and Anti-Strike Legislation

Officers of the 14 principal railroad labor organizations, including the four train service brotherhoods, at a conference with Samuel Gompers of the American Federation of Labor at Washington on December 29, adopted a declaration of principles expressing their dissatisfaction with the President's action in relinquishing control of the railroads as of March 1 and also their opposition to the anti-strike provisions of the Cummins bill, but saying nothing regarding the wage demands which most of them have pending before the

Railroad Administration but which have been held in abeyance, returned, but the labor leaders recently have been expressing greater concern over the proposed anti-strike law, which would take away much of their power to force wage increases by threatening to strike. The declaration adopted at the conference with Mr. Gompers says:

"That it is the sense of the conference that the control of the railroads should be exercised by the government of the United States for a period of not less than two years, that a proper test may be made as to government control.

"That such test has not been given a fair opportunity during the war times or since.

"This conference is opposed to legislation making strikes of workers unlawful. It is the sense of this conference that penalty clauses in pending legislation on railroads against workers ceasing their employment should be eliminated.

"That the conference favors the enactment of beneficial features of the bills which tend to establish better relations between employees and carriers.

"That the beneficial clauses should be extended to the sleeping car and Pullman Company employees."

MEETINGS AND CONVENTIONS

American Society for Testing Materials.—The annual meeting of this association will be held at the New Monterey hotel, Asbury Park, N. J., beginning on Monday, June 21, 1920. This is a departure from the precedent of long standing of holding the annual meeting at Atlantic City.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

- AIR-BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 163 Broadway, New York City.
- AMERICAN RAILROAD ASSOCIATION, SECTION III.—MECHANICAL.—V. R. Hawthorne, 431 South Dearborn St., Chicago.
- AMERICAN RAILROAD MASTER TINNERS' COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—O. E. Schink, 445 W. Fifth St., Peru, Ind.
- AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—R. D. Fletcher, Belt Railway, Chicago.
- AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 21, 1920, New Monterey Hotel, Asbury Park, N. J.
- AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
- AMERICAN STEEL TREATERS' SOCIETY.—Arthur G. Henry, Illinois Tool Works, Chicago.
- ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.
- CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 841 Laylor Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.
- CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—Thomas B. Koeneke, secretary, Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
- CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—H. J. Smith, D. L. & W., Scranton, Pa.
- INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, C. H. & D., Lima, Ohio
- INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. G. Crawford, 542 W. Jackson Blvd., Chicago.
- INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn.
- MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York. Convention May 25-28, Curtis Hotel, Minneapolis, Minn.
- MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION OF U. S. AND CANADA.—A. P. Dane, B. & M., Reading, Mass.
- NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.
- RAILWAY STOREKEEPERS' ASSOCIATION.—J. P. Murphy, Box C, Collinwood, Ohio.
- TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

RAILROAD CLUB MEETINGS

Club	Next Meeting	Title of Paper	Author	Secretary	Address
Canadian	Jan. 13, 1919	Graphic Production Control	E. T. Spidy	W. A. Booth	131 Charron St., Montreal, Que.
Central	Jan. 9, 1919	Continuation of discussion on November paper, Locomotive Operations, Annual reports and installation of new officers			
Cincinnati				H. D. Vought	95 Liberty St., New York.
New England	Jan. 13, 1919	Steel Specifications		H. Boutet	101 Carew Building, Cincinnati, O.
New York	Jan. 15, 1919	Dinner; Addresses by Hon. E. C. Stokes and Hon. Job E. Hedges	F. A. Weymouth	W. E. Cade, Jr.	683 Atlantic Ave., Boston, Mass.
Pittsburg	Jan. 22, 1919	Express Transportation	D. N. Gibson	H. D. Vought	95 Liberty St., New York.
St. Louis	Jan. 16, 1919	Idealism in Business	Rev. Z. B. T. Phillips	J. D. Conway	515 Grandview Ave., Pittsburgh, Pa.
Western	Jan. 19, 1919	Preparation of Locomotives at Engine houses and Shops and Its Relation to Fuel Economy		B. W. Frauenthal	Union Station, St. Louis, Mo.
			I. R. Pyle	J. M. Byrne	916 West 78th St., Chicago.

PERSONAL MENTION

GENERAL

P. G. WINTER has been appointed mechanical valuation engineer of the Chicago, Milwaukee & St. Paul at Chicago, succeeding W. F. Lynaugh, assigned to other duties.

R. G. BENNETT, master mechanic of the Pennsylvania at Pittsburgh, Pa., has been appointed superintendent of motive power of the Central division, with headquarters at Williamsport, Pa., succeeding E. W. Smith. Mr. Bennett was born at Brighton, England, on March 31, 1882. He entered the service of the Pennsylvania Railroad in 1900 as a machinist apprentice in the Erie, Pa., shops, completing his apprenticeship at the Renovo, Pa., shops four years later. He graduated from Purdue University in 1908 as a bachelor of science in mechanical engineering and in 1915 he was given the degree of mechanical engineer. While attending college, he worked during the summer months as a machinist, draftsman and inspector and in November, 1908, was appointed motive power inspector of the Monongahela division. He was later transferred to the maintenance of way department and then to the test department at Altoona. In May, 1916, he went to Chambersburg, Pa., as assistant master mechanic of the Cumberland Valley Railroad, but returned to the Pennsylvania Railroad in February, 1917, as assistant engineer of motive power of the Central division and later in that year he was appointed master mechanic at Pittsburgh.

R. G. Bennett

F. S. DEVENY, assistant road foreman of engines of the Baltimore & Ohio, Chicago Terminal, has been promoted to the position of trainmaster at Chicago, succeeding J. W. Dacy, deceased.

LUKE J. GALLAGHER, locomotive engineman on the Northern Pacific, has been promoted to the position of road foreman of engines of the Rocky Mountain division, with headquarters at Missoula, Mont., succeeding H. E. Day, who has been granted leave of absence.

J. A. MARSHALL, road foreman of engines of the Northern Pacific, at Duluth, Minn., has been appointed acting master mechanic of the Lake Superior division, with the same headquarters, succeeding J. E. Goodman, who has been given a temporary leave of absence.

S. E. MUELLER, general foreman in the locomotive department of the Chicago, Rock Island & Pacific, at Cedar Rapids, Iowa, has been promoted to master mechanic of the Dakota division, at Estherville, Iowa, succeeding R. J. McQuade, who has resigned.

F. S. ROBBINS has been appointed master mechanic of the Pennsylvania at Pittsburgh, Pa., succeeding R. G. Bennett.

G. E. PASSAGE, traveling engineer of the Chicago, Milwaukee & St. Paul, with headquarters at Chicago, has been appointed trainmaster of the Illinois division at Savannah, Ill.

E. O. SMITH, master mechanic on the St. Louis & Hannibal, with headquarters at Hannibal, Mo., has been appointed to the newly-created position of master mechanic on the Louisiana & North West, with office at Homer, La.

CLARENCE E. TROTTER, whose appointment as master mechanic of the Lake Erie & Western, with headquarters at Lima, Ohio, was announced in these columns last month, was born on March 29, 1890, at Plainfield, Ind. He was graduated as a mechanical engineer from Purdue University in 1912. He then served a special apprenticeship with the Cleveland, Cincinnati, Chicago & St. Louis and during this time spent eleven months on the Lake Erie & Western investigating the merits of different boiler compounds, with respect to the cost of locomotive maintenance. On completing the apprenticeship course he was sent to the Mexican border as an inspector of material and during the war served overseas as a first lieutenant and a captain in the Forty-second division. In June, 1919, he was appointed assistant enginehouse foreman of the Cleveland, Cincinnati, Chicago & St. Louis, at Brightwood (Indianapolis), Ind., and for a time was acting night enginehouse foreman. He was recently appointed master mechanic of the Lake Erie & Western, the Fort Wayne, Cincinnati & Louisville and the Northern Ohio, as previously noted.

N. P. WHITE, roundhouse foreman of the Northern Pacific at Duluth, Minn., has been promoted to master mechanic of the Minnesota division at Staples, Minn., succeeding William Radke, deceased.

C. H. WILCKEN has been appointed traveling engineer and trainmaster of the Denver & Rio Grande, with headquarters at Helper, Utah, succeeding G. W. Bourne, transferred.

SHOP AND ENGINEHOUSE

JOHN B. DAVIS has been appointed night roundhouse foreman of the Erie at Meadville, Pa., succeeding C. Kinney, transferred.

F. C. MOELLER, roundhouse foreman of the Chicago, Rock Island & Pacific, at Blue Island, Ill., has been promoted to general foreman in the locomotive department at Cedar Rapids, Iowa, succeeding S. C. Mueller.

ALDEN MORGAN has been appointed erecting shop foreman of the Erie at Huntington, Ind., succeeding P. F. Myers, resigned.

PURCHASING AND STOREKEEPING

F. E. JOHNSON, storekeeper of the Baltimore & Ohio at Mt. Clare, Baltimore, Md., has been appointed assistant general storekeeper at Baltimore.

TOM MOORE, general storekeeper of the Virginian at Princeton, W. Va., has been appointed purchasing agent, succeeding A. B. Lacy, resigned. D. C. King succeeds Mr. Moore.

T. H. RYAN, local purchasing agent at New Orleans, La., of the Vicksburg & Alabama, has been appointed purchasing agent of that road and of the Louisiana & Mississippi Transfer and the Vicksburg, Shreveport & Pacific.

H. SHOEMAKER, district storekeeper of the Northwest District of the Baltimore & Ohio, with headquarters at Cleveland, Ohio, has been appointed storekeeper at Mt. Clare, Baltimore, Md., succeeding F. E. Johnson.

OBITUARY

ALFRED E. CORBETT, locomotive foreman of the Canadian National Railways at St. John, N. B., was accidentally killed while at work on January 16. He was 34 years old and had been in the employ of the Canadian National for about eight years.

SUPPLY TRADE NOTES

The American Car & Foundry Company has begun to purchase approximately \$200,000 worth of machine tool equipment.

H. H. Hendricks, formerly connected with the Ryan Car Company, Chicago, has been appointed a salesman for the Camel Company, Chicago.

John W. Fogg, sales representative of the Boss Nut Company, Chicago, with office in that city, has been promoted to railroad sales manager, with the same headquarters.

Irving H. Jones of Chicago, has become associated with the machinery department of Joseph T. Ryerson & Son, and will specialize in sales engineering work for that company.

The Van Dorn Girder Plate Company, manufacturer of railway car appliances, has removed its general offices from 2325 South Paulina street, Chicago, to 608 South Dearborn street.

C. A. Pinyerd, supervisor in the Chicago office of the Safety Car Heating & Lighting Company, New York, has been appointed sales representative, with the same headquarters.

The Cleveland Twist Drill Company has purchased a 17-acre factory site on the eastern outskirts of Cleveland, Ohio, to provide for factory enlargements which it expects to make in the near future.

J. F. Comee, formerly associated with the Camel Company as representative at Chicago, has been appointed manager of sales, with headquarters at Chicago, for the Hutchins Car Roofing Company, Detroit, Mich.

William A. Benson, formerly associated with the Adams & Westlake Company, Chicago, has been appointed assistant manager of sales in the Chicago district for the Hanna Locomotive Stoker Company, Cincinnati, Ohio.

Hal R. Stafford, who has been chief engineer of the Franklin Railway Supply Company, Inc., since this company took over the Economy Devices Corporation, died at his home in Plainfield, N. J., on December 9.

C. R. Ellicott, assistant eastern manager at New York of the Westinghouse Air Brake Company, Pittsburgh, Pa., has been promoted to eastern manager, with headquarters at New York, succeeding Joseph R. Elliott, retired.

E. A. Woodworth, secretary of the Committee on Mechanical Standards of the United States Railroad Administration, has resigned to become special representative for the Chicago Pneumatic Tool Company, with office at Chicago.

E. E. Griest, formerly master mechanic of the Fort Wayne (Ind.) shops of the Pennsylvania Lines West, has been appointed general superintendent of the Chicago Railway Equipment Company, with headquarters at Chicago.

R. B. Jones and E. E. Hart, both formerly of the Dale-Brewster Machinery Company, Inc., Chicago, have resigned and organized the Industrial & Railroad Supply Company, with headquarters at 114 North Desplaines street, Chicago.

Edward D. Kilburn, who since March 16, 1917, has been New York district manager of the Westinghouse Electric & Manufacturing Company, was recently elected vice-president and general manager of the Westinghouse Electric International Company, New York, which was formed in the spring of 1919 to succeed the Westinghouse Electric Export Company.

The American Steam Conveyor Corporation, Chicago, announces that the Atlas Machinery & Supply Company, 1416 Syndicate Trust building, St. Louis, Mo., is now handling the sale of the American steam ash conveyor in the St. Louis territory.

The Schaefer Equipment Company, Pittsburgh, Pa., manufacturers of railway materials, has recently completed arrangements with the International Equipment Company, Ltd., Montreal, Quebec, to handle its manufactures and sales in Canada.

A. P. Van Schaick, special representative at Chicago of the American Chain Company, Inc., Bridgeport, Conn., has been appointed assistant general sales manager of the company, with headquarters at the Grand Central Terminal New York.

The Duntley-Dayton Company, Chicago, manufacturers of pneumatic and electric tools, has changed its name to The Duntley Pneumatic Tool Company. There is no change of officers, the change in corporate title having been for business reasons.

The St. Louis Machine Tool Company is building an addition to its plant at St. Louis, Mo., which will add about 13,000 sq. ft. to the floor space and practically double the capacity for the manufacture of grinding, polishing and tapping machines.

Fred C. Dunham, formerly assistant to the president of the National Railway Appliance Company, has been elected vice-president of the Hutchins Car Roofing Company, Detroit, Mich. Mr. Dunham's headquarters are 103 Park avenue, New York.

Charles Nourse, until recently in charge of the engineering department of the Heald Machine Company, Worcester, Mass., has severed his relations with that company to accept a position with the Lombard Machine Company, Worcester. Victor Bergstrom succeeds him.

The General American Tank Car Company, Chicago, will build a plant on the Mississippi river, a short distance above New Orleans, La., to cost \$1,000,000. The new plant will include a machine shop and steel foundry for the manufacture of tank cars, gondolas, flat cars, etc.

The Mid-Continent Equipment & Machinery Company has been organized at St. Louis, Mo., to deal in railway supplies. F. W. Glaser is president, R. H. Wilson vice-president, and J. B. Fidler secretary-treasurer. The offices of the new company will be in the Security building.

The Firth-Sterling Steel Company, McKeesport, Pa., will move its New England headquarters from 35 Oliver street, Boston, Mass., and after February 1 will occupy a new warehouse at 85-91 West First street, South Boston, where complete stocks of Blue Chip high-speed steel and other Firth-Sterling tool and die steels will be carried.

D. L. Eubank has been appointed district manager in charge of the Cincinnati office of the Galena-Signal Oil Company. Mr. Eubank was born November 24, 1869, and was in the employ of the Chesapeake & Ohio from September, 1889, to February, 1911, as locomotive fireman, engineman and road foreman of engines. In February, 1911, Mr. Eubank accepted a position as mechanical expert with the Galena-Signal Oil Company.

Albert Schmid, consulting engineer for the Westinghouse Electric & Manufacturing Company, died in New York on December 31, 1919. Mr. Schmid was closely identified with the early development of electrical machinery in the United States and was also prominent in the electrical world of France, Switzerland, Italy and Great Britain. At the time

of his death he also represented the Westinghouse Lamp Company and had general supervision of its interests abroad.

Frank O. Wells, president of the Greenfield Tap & Die Corporation, and one of the prominent figures in the screw thread industry in the United States, has sold his entire holdings to Frederick H. Payne, vice-president. Mr. Wells retires as president and member of the board of directors, but will remain with the corporation in an advisory capacity. Mr. Payne has been elected president and F. G. Echols, vice-president and general manager, has been elected a director of the corporation.

The Gustin-Bacon Manufacturing Company, Kansas City, Mo., has purchased all machinery and equipment formerly used by the Emery Pneumatic Lubricant Company of St. Louis, Mo., and has also acquired the exclusive rights to the manufacture and sale of the Emery brake cylinder lubricant. E. A. Emery, the originator of the Emery brake cylinder lubricant formula, has become associated with the Gustin-Bacon Manufacturing Company and has direct charge of the manufacture of this product.

Owing to the rapidly increasing use of the American staybolt and the reduced body staybolts by the railroads and industrials of this country, Benson & Co., with general offices at 50 Church street, New York, has been organized to promote the sales and service of the American Flexible Bolt Company products. R. W. Benson, general sales manager, is president of the new company. Both companies will maintain engineering service organizations to study locomotive boiler staybolt problems and aid in their solution.

Arthur W. Wheatley, who was elected president of Armstrong Whitworth (of Canada), Ltd., in November of last year, is now in full control and direction of the Longueil works. The works have, since their inception, been engaged in the manufacture of tool steels, small tools, railway tires, etc., and with the cessation of hostilities the policy and energies of the firm were directed toward the further development of their products, especially of railway material, for which there is a heavy demand. It is proposed also to develop the manufacture of all-steel wheels for rolling stock.

L. R. Custer, formerly development engineer for the Midvale Steel & Ordnance Company, has been elected a vice-president of the Cambria Steel Company. He was born in Altoona in 1873, and graduated from Cornell University in 1902. His first work was as a machinist for the Pennsylvania Railroad. He later was in the employ of the Baldwin Locomotive Works, and then served as a draftsman for the Jones & Laughlin Steel Company, Pittsburgh. He entered the service of the Homestead Steel Company as a construction foreman and in 1914 was made superintendent of the armor plate department. During the early part of the war he developed the ordnance department of that company. Shortly before the close of the war he left the Homestead Company to go with the Midvale Company.

Major J. L. Hays has been appointed electrical engineer of the Stone Franklin Company, with office at 18 East Forty-first street, New York. Major Hays has a wide experience in electrical engineering problems, particularly as regards electric car lighting. He was graduated from Lehigh University in 1909, with the degree of electrical engineer. Upon graduation he joined the electrical department staff of the Baltimore & Ohio and worked successively as mechanic, draftsman, inspector, general foreman and assistant engineer. From the Baltimore & Ohio he went to the Seaboard Air Line as electrical engineer, and when war was declared with Germany he was commissioned as major in the Quartermaster Corps and was the officer in charge of the electrical section of the engineering branch, responsible for electrical construction for the army in the United States.

The business and property of the O. S. Walker Company, Worcester, Mass., manufacturers of grinding machines and magnetic chucks, has been sold by Oakley S. Walker to a group of men prominently connected with the machine tool and supply business, and the reorganization of the company has been completed. The name of the company will remain unchanged and the new officers are: president, W. B. Mc-Simmon, Boston; vice-president, J. H. Drury, Athol; general manager, secretary and treasurer, Clayton O. Smith. The new ownership brings with it increased financial resources, which will make possible future development and increase of the business. The company manufactures grinding machines of various types and magnetic chucks used in holding iron and steel parts while they are being ground or machined.

John C. Barber, founder and president of the Standard Car Truck Company, Chicago, and inventor of over 75 railway truck appliances, died in Los Angeles, Cal., on December 27, 1919. He was

J. C. Barber

the inventor of a device for limited lateral play in railway trucks which has been applied to about 20 per cent of the freight cars of the country. Mr. Barber was born in St. Lawrence county, New York, on December 12, 1844. In September, 1861, he enlisted in a Wisconsin regiment and served throughout the Civil war. In 1865 he began his railway career with the Chicago & North Western in its locomotive and car-building department at Fond du Lac, Wis., filling various positions

there for six years. He then became connected with the mechanical department of the Northern Pacific shops at St. Paul, Minn., and in 1873 was appointed superintendent of the car department of the Missouri, Kansas & Texas, with headquarters at Sedalia, Mo. From 1883 to 1885 he was superintendent of the Rio Grande division of the Texas & Pacific, with office at Fort Worth, Tex. From the latter date until he resigned to market his inventions, in 1896, he was in charge of the car department of the Northern Pacific at St. Paul, Minn. It was while serving in this latter capacity that he perfected his invention for lateral roller motion trucks. In 1898 he organized the Standard Car Truck Company, and of this organization he retained the presidency until his death.

Jenkins Brothers in the near future will increase the manufacturing facilities for the production of Jenkins valves by the establishment of a plant in Bridgeport, Conn. The manufacture of Jenkins disks, sheet packings, pump valves and other mechanical rubber goods will be continued at Elizabeth, N. J. Alterations and additions to the brass valve department of Jenkins Brothers, Ltd., Montreal, the Canadian branch, have recently been completed, and a new iron valve foundry building 80 ft. wide by 192 ft. long is now in course of construction. This plant supplies Canada and foreign countries, while the Bridgeport plant will manufacture valves for use in the United States and insular possessions.

Lieut. Vernon S. Henry who served prior to the war, in an engineering capacity with the Safety Car Heating & Lighting Company, New York, has re-entered the service of

that company and is now connected with the Philadelphia office as sales representative. Lieutenant Henry is a graduate of Stevens Institute of Technology and at the outbreak of the war attended the first training camp at Fort Myer, Va., and received his commission as first lieutenant in August, 1917. He went to France the following November and was in charge of automatic rifles in the A. E. F., remaining there until May, 1918. He then returned to the United States to assist in the production of machine gun tripods, model 1919, and for his development in this work he afterwards received a citation for meritorious and conspicuous service. In 1918 he returned to France and was in charge of the development of machine gun and anti-aircraft material until discharged from the service in February, 1919.

The Locomotive Terminal Equipment Association, Inc., has recently been organized by a group of manufacturers and dealers in equipment for use in locomotive terminals, for the purpose of studying the needs for improvement in locomotive terminals in order to secure quicker handling, repairing and turning of locomotives. In the distribution of such data as is developed from the surveys made or from other sources, a policy of impartiality is to be followed and no special advantage is to accrue to any individual firm or corporation that may be a member of the association. The officers are: President, William R. Toppan, manager railroad department, William Graver Tank Works; vice-president and secretary, Bruce V. Crandall; treasurer, John S. Maurer, secretary and treasurer, National Boiler Washing Company; general counsel, Frank J. Loesch. The board of directors consists of the following seven members: William R. Toppan, Bruce V. Crandall, Spencer Otis, president, National Boiler Washing Company; William Robertson, William Robertson & Co.; Frank W. Miller, president, F. W. Miller Heating Company; Robert A. Ogle, president, Ogle Construction Company, and Norman S. Lawrence, vice-president and assistant sales manager, Whiting Foundry Equipment Company. The association has headquarters at the office of the secretary, room 1824, Lytton building, Chicago.

Dr. M. E. Pennington has joined the staff of the American Balsa Company, Inc., New York, manufacturers of Balsa wood products, including insulation material. She will be in charge of research and development work. Dr. Pennington graduated from the University of Pennsylvania where she specialized in chemistry and received the degree of P.D. She had charge of the chemical department of Women's Medical College of Pennsylvania and later of the City Bacteriological Laboratory of the Department of Health and Charities of the City of Philadelphia; she then established her own clinical laboratory, making a specialty of doing scientific research work in connection with medical research work of practicing physicians. Since 1905 she has been employed by the U. S. Department of Agriculture, having entered the service on part time, doing special research work, and later took up the preservation of foods by better handling methods, especially the application of refrigeration to all phases of the distribution of foodstuffs. Dr. Pennington gradually gave up her various other interests and has devoted herself entirely to that line of work under the auspices of the Department of Agriculture since 1907, when the Research Laboratory formally was established as an organization of the department. Dr. Pennington is the author of a number of articles which have appeared in the technical press and elsewhere, dealing with chemistry, bacteriology and botany. Since her connection with the Department of Agriculture a number of articles by Dr. Pennington on the preservation of foodstuffs by low temperatures, the effect of better methods of handling perishables, also on refrigerator cars, have appeared in the *Railway Mechanical Engineer*.

CATALOGUES

PIPE CUTTING AND THREADING TOOLS.—A new catalogue, No. 12, of Beaver cutting and threading tools for pipe has been published by the Borden Company, Warren, Ohio. It contains list prices and data for complete tools and extra parts and a large number of illustrations.

PORTABLE WELDING OUTFITS.—Three types of trucks for transporting portable oxy-acetylene and oxy-hydrogen welding and cutting equipment manufactured by the Davis-Bournonville Company, Jersey City, N. J., are described and illustrated in an eight-page pamphlet. One of these is a cabinet truck which provides permanent mountings for the regulators and gages within a steel locker, which also affords space for the torches, hose, accessories and supplies. The other two are open trucks, one having large wheels especially fitted for traveling on rough ground and the other having small wheels, designed for use on floors, pavements and level ground.

CASEHARDENING MATERIALS.—Bell & Gossett Company, Chicago, Ill., briefly describe several products manufactured by them for use in casehardening, in a pamphlet entitled Casehardening Materials. These specialties include a carbonizer known as Hi-Carbon Compound; B-G Compound for hardening, serving the same purpose as cyanide without giving off deadly fumes; Enamelite, which when applied to low carbon steel will prevent the steel from absorbing carbon during the casehardening process, producing soft areas where they are desirable; Bath-ite, a compound used for preheating between 1,200 and 1,600 deg. F., making it possible to heat the work to a uniform temperature away from the air in order to eliminate scale and oxidization; and Cleancoat, for scouring the steel heated in lead baths.

FURNACES FOR HEAT TREATING.—Catalogue No. 75, containing 80 pages, 8½ in. by 11 in., has been published by the Chicago Flexible Shaft Company, Chicago, and is devoted to the Stewart gas and oil furnaces, which are adapted to a wide range of heat treating operations. These furnaces burn only gas or oil and are built in many designs and sizes to meet a great variety of conditions, the line being divided into oven, crucible and forge types. Several special features of the Stewart furnaces are described, including a U-shaped bottom slab which makes it unnecessary to use muffles and gives to the furnace area the advantage of the transfer of heat through the bottom and sides of the enclosure. The many types of furnaces are separately described and illustrated, specifications and prices being given also, in addition to which the book contains instructions as to the proper methods of hardening steel, carbonizing, cyanide treating, etc.

CELFOR DRILLS.—Putting Mettle Into Metal is the title given by the Clark Equipment Company, Buchanan, Mich., to a booklet describing the making of Celfor drills and precision tools, and telling of various innovations which the company has put into effect for the benefit of employees, which tend to give them a keener interest in their work and promote harmony between employer and employees. The booklet contains numerous illustrations, one colored two-page illustration showing a general view of the plant and grounds which have been made into an attractive park. Other illustrations show a theatre which is operated by the company without profit and is used by the employees for a great variety of activities; a hospital which is conducted by a hospital association formed among employees, and several homes which are typical of a large number built by the company and sold to employees at actual cost.

Railway Mechanical Engineer

VOLUME 94, NUMBER 2

New York—FEBRUARY, 1920—Chicago

ESTABLISHED IN 1832

Published Monthly by Simmons-Boardman Publishing Co., Woolworth Building, New York, N. Y. Subscription price, United States, Canada and Mexico, \$2.00 a year; foreign countries, \$3.00 a year. Entered as second-class matter, January 27, 1916, at the post office at New York, N. Y., under the Act of March 3, 1879.

TYPICAL FIREBOX WITH COMBUSTION CHAMBER CONVERTED
FROM COAL TO OIL BURNING

This is the shape of the flame with the back end oil burner.

This is the shape of the flame with the front end oil burner.

The back end burner gives approximately twice the flame length.
Increased flame length means increased economy.

Teeming One of Our Electric Crucible Furnaces **Ludlum Electric Crucible Steel**

Every visitor to our plant tarries awhile here—for it is very fascinating to watch a Ludlum Electric Crucible Furnace teeming into the ladle.

The Ludlum Electric Crucible Furnace was developed entirely by us, to meet our own individual requirements. It produces unexcelled quality of absolutely controlled analysis.

Do you realize that the majority of twist drill and milling cutter manufacturers in America are using Ludlum Steels?

Among the Ludlum "Consistently Uniform" Brands are

MOHAWK EXTRA

High Speed Steel

ALBANY

Alloy Tool Steel

HURON

Alloy Die Steel

YUMA

Chrome Magnet Steel

POMPTON

Carbon Tool Steel

ONEIDA

Oil Hardening Tool Steel

TETON

Ball Bearing Steel

SEMINOLE

"Fool Proof" Chisel Steel

LUDLUM STEEL COMPANY

General Offices and Works
WATERVLIET, N. Y.

This LUDLUM—Text Book is a complete treatise on the various tool steels. It describes the correct method of forging, hardening, tempering, annealing. It contains accurate calculation tables and other valuable information. Just ask us for it and it's yours, free.

"Prompt shipment from warehouse stock at Watervliet, N. Y., or Detroit, Mich.—handled through our District Offices."

There are many varieties of railway supply salesmen. It is quite noticeable, however, that gradually but steadily these men are becoming less and less of the pure salesmanship type, and are more and more taking on the functions of engineering experts and practical service men. Service, not price, is the prime consideration in the eyes of the keen and far-sighted railroad buyer, and the railway supply manufacturer has awakened to a realization of this and is organizing his forces accordingly. It is indeed not out of place here to note that some of the railway supply manufacturers have helped to bring about this condition by being forced to demonstrate their devices thoroughly and then to follow them up closely in service when they were finally adopted.

Use the Railway Supplymen

The personal factor is therefore becoming of less and less importance in negotiating sales; the hard-headed railway officer is looking for real and lasting results—in fact, he must do this in order to overcome the effect of the rising costs and hold his job, as he will make a desperate fight to prevent being separated from the payroll. Many mechanical department officers realize the opportunity of securing valuable information and assistance from the representatives of the manufacturers, who are constantly traveling about the country and keeping in touch with the best practices on the most progressive roads.

For some reason, however, the railway repair shop authorities do not take this same attitude toward the representatives of machine tool and small tool manufacturers. It must frankly be admitted that Mr. Armstrong, in his communication on "Open the Shop Doors," on another page, has hit squarely on the head a weak spot in the average railway repair shop organization. Many of the representatives of the machine tool and small tool manufacturers—most of them in fact—can qualify as experts on machine tool operation and shop practices. They can bring to the attention of the railway shop management good methods and practices which are used in other lines of industry (which may be applied to

advantage in railway shops) and which might otherwise never come to the attention of the railway shop authorities.

It may be argued that showing courtesies to these representatives will take valuable time from already overworked officers and foremen. If so it is time to reorganize the staff or make additions to it, for this condition indicates a tendency to get into a rut, and, like the ostrich, bury one's head in the sand. No railroad shop officer or foreman should be so busy that he cannot give time to studying how to improve the work of his shop or department.

Some time ago the Railroad Administration adopted as standard one type of hose coupling for steam heat lines. The matter was decided by a committee and its choice certainly is representative of the equipment used on some of the largest roads in this country. Nevertheless, there has been considerable ad-

verse criticism of the coupling adopted and since there is a possibility that the Mechanical Section of the American Railroad Association may take up the adoption of a standard for the association, the matter should not be dismissed until the relative merits of various types are definitely established.

The hose couplings which have been most generally used are of two classes, one having a positive lock and the nipple set at an angle of 30 deg. with the face of the coupler, and the other type without the positive lock and the angle of the nipple 20 deg. The latter type was selected as the administration standard. The principal criticism of this coupling has been that the angle of the nipple is so small that it causes excessive bending of the hose when coupled, thereby setting up unnecessary stresses and often causing failures. Furthermore, it is claimed that the larger angle facilitates coupling and the positive lock increases the life of the gaskets because it keeps them tightly closed.

In favor of the non-positive lock and the 20-deg. angle it is claimed that the locking parts are easier to manipulate

and that the loss due to the hose being torn off when cars are uncoupled without separating the hose is reduced. It is doubtful whether the latter argument has much weight, because in almost every case when the hose is not uncoupled by hand it is torn off before the couplings part. That the angle of 20 degrees is rather small is shown by the fact that it is specified as the minimum in the recommended practices adopted by the Master Car Builders' Association.

The cost of steam hose is a considerable item and it should be well worth while for the railroads to keep careful records of the comparative service life secured with different types of couplings, in order that accurate data may be available in case it is desired to standardize these parts.

The mechanical department has in the past, and particularly in pre-war days, been looked upon as a more or less

**Mechanical
Department
After March 1**

necessary evil—as an expense and not as an earning factor. In too many cases the heads of the mechanical department have adopted a subservient attitude and have stood for conditions that in the interests of the railroad property as a whole they should have opposed determinedly and have insisted upon being changed or corrected.

What was the result? Railroad executives waked up too late to the realization that proper maintenance and upkeep of equipment and facilities is a really vital factor in railroad operation. Roads which, like the Delaware, Lackawanna & Western, had taken a real pride in keeping their equipment in as nearly 100 per cent condition as possible, had a fairly comfortable time two or three years ago when the great majority of roads were badly up against it because of the low standard of maintenance of their equipment.

Railroad officers—many of them—deeply resented the fact that the head of the mechanical department of the Railroad Administration, an outsider so far as railroad shop practices are concerned, found it necessary to step in and show up some of their inadequate facilities and equipment. There was a real reason for it, however; it would never have been necessary in many instances if the mechanical department officers had had the courage of their convictions, and had carried the issue to the last ditch with their superior officers in pre-war days.

Mechanical department officers have been prone to criticize and blame the executive officers for not giving them the proper support in their efforts to improve the equipment and its maintenance. This is foolish. It simply indicates that the mechanical department head has lacked force or has not assembled data which would clearly demonstrate his contentions. The executive officers cannot be expected to be fully acquainted with the details of the technical departments; they have heavy responsibilities to bear in directing the properties and they rely upon their subordinates to make their needs known in such a way as fully to justify them in granting authority. It is here that mechanical department officers have fallen down.

Conditions during the past three years have forcefully demonstrated the wisdom of keeping the equipment in first-class condition and of providing adequate facilities for its care. It is not going to be so difficult for the mechanical department officer to drive home his point in the future as it has been in the past—but he must present his argument and data in such a way as to make it really effective and then keep persistently at it, in season and out of season. If he fails, the chances are that in the last analysis he is at fault in not presenting his case in the right way.

The roads go back to their owners on March 1. Congress is doing its best to get a satisfactory law enacted. It ought not to be too harshly criticised if the measure falls short of a reasonable degree of perfection. Many different and con-

flicting elements have been exceedingly active in trying to have their ideas adopted, and the suggestions have ranged from extreme radicalism to standpat conservatism.

Railroad officers must get this, however. Conditions as to regulation, the attitude of the public, labor and almost every other element have changed radically from those existing before the war. Railroad men must realize this, and must fairly and squarely meet the new conditions with an open mind and a determination to make good in a large way. The interests of the public, the employees, the security holders and the management are so intimately interwoven that putting on blinders and attempting to operate in the old rut will spell disaster.

You may have the idea that after March 1 you will be free of certain restraints that may have rankled in your mind. You may reason that you can drastically handle some things which are not quite as you would like to have them. You may think you can go back into the rut of some of your favorite pre-war methods and practices. May we give just a word of warning? The railroad game is going to be a bigger one than ever before. It will require big men to direct it. You may be one of those big men—but if so, you will have to study and know human nature; you will have to use your head and determinedly stand behind your guns in directing your department with a big broadminded and open-minded attitude. You must view your task in the light of a profession and not as a job.

Repair work on locomotives has always been delayed more or less both in back shops and roundhouses by the difficulty in

**Foundry
Aids
Repair Shop**

getting iron and steel castings when needed. This difficulty is greater now than ever before because of the recent steel and coal strikes. Even in pre-war days, however, the process of getting castings through the usual channels of stores department and purchasing agent was exasperatingly slow from the shop foreman's point of view. Often the storekeeper at a local shop would have to get in touch with all the other storekeepers on the system before an order could be taken, and when it was finally approved and placed with a foundry the deliveries were very unsatisfactory. Every one is familiar with one result of slow material deliveries—namely, the robbing of various parts from one locomotive to complete another, a costly practice which should not be tolerated. Locomotives must not be delayed in the shop, however, and there is a serious temptation for the men responsible for output to rob the desired part from a locomotive due out some time later. Consider, for example, a locomotive that comes to the shop with a cracked front deck casting not mentioned on the work report. If the casting is cracked too badly to be welded and there is none in stock, there will be a serious delay in getting the locomotive back into service, with the attendant loss of revenue.

One way to avoid the above difficulty lies in the establishment of a foundry in conjunction with the repair shop. Experience has shown that where conditions are favorable it is possible to operate not only a grey iron but also a steel foundry to furnish all the smaller castings, such as driving boxes, cylinder heads, front frames and deck castings, needed. Good quality grey iron castings are now being made in railway foundries, and the relatively greater difficulty in making steel castings has been overcome, as shown by the satisfactory results of rigid physical and chemical tests. With suitable foundry facilities no locomotive would be held up for machine parts, since they could be cast in the local foundry in less than 24 hours. The unit cost of the castings thus made would be high, due to their light weight, and the saving effected has proved in an actual case sufficient to pay all carrying charges on the investment involved.

Not only is it possible to make standard castings promptly, but a pattern of any special part can be made quickly and be cast, whereas the old method of ordering from an outside foundry would require several weeks. There is danger of overdoing a good thing in the matter of special castings, and none should be made unless authorized by the master mechanic. A careful check should also be made of standard castings and none delivered to the shopmen without orders signed by their foremen. Taken altogether, the great convenience of having castings when needed, the reduction in the amount of stock carried on hand and the resulting economy, make the foundry a most valuable adjunct to a large railway repair shop.

It is essential to the proper development of the railroads—in the eastern section of the United States particularly—that mechanical engineers and operating officers give careful consideration to the type of locomotives which they expect to build in the immediate future. It is quite probable, indeed imperative, that there be built a great amount of motive power in the next several years, and with the traffic becoming more and more dense the problem becomes one not only of adequate volume of motive power, but also of providing this power in the minimum number of units consistent with a mobile organization.

Selecting the Type of Locomotive

Just as it is necessary to have a tool of adequate capacity in the shop in order to effect economical production, so also is it necessary to have motive power in units of adequate size economically to perform the service required of them. It is an indisputable fact that 120,000 lb. of tractive power may be more economically maintained and operated if contained in only two units each having a tractive effort of 60,000 lb., than would be the case if the same amount of power were distributed in three units of 40,000 lb. each. The saving in fuel and cost of repairs would be large enough to make such a course desirable, but when, in addition to these savings, the savings in wages of engine crews is considered it is obvious that the fewer units in which the power is contained, the lower the cost per pound of tractive effort will be.

This, however, presents a problem involving track conditions and terminal and transfer point requirements. It will require the best engineering brains in the railroad field to determine the most suitable type of locomotive for a specific service and then to design it to meet the conditions under which it will operate. The successful operation of some heavy switching locomotives recently built for use on one of the larger southern railroads is evidence of the great possibilities lying in this direction. Economy and utility demand that this phase of locomotive design be given the most careful attention.

NEW BOOKS

Complete Practical Machinist. By Joshua Rose, M. E. 547 pages, 5 in. by 7½ in., illustrated, bound in cloth. Published by Henry Carey Baird & Co., Inc., 2 West Forty-fifth street, New York.

This book is the twentieth edition of the work and is greatly enlarged in scope. It treats of practical machine shop methods in the language of the shop man and gives in concise form many explanations, with suitable illustrations, of the uses of the tools of the shop. As in previous editions the book gives practical instructions in the use of metal working tools and tells precisely how the various operations should be performed. In addition to a description of cutting tools and their uses there are several chapters on the use of machine tools and their attachments. The very important subject of cutting speed and feed is treated in a comprehensive manner which should prove to be of great value to the machinist. Other subjects which are presented in a practical

form are boring tools for lathe work, boring bars, screw cutting tools, twist drills, taps and dies, tool steel, vise work tools and slotting tools. The turning of eccentrics, drilling in the lathe, fitting connecting rods, milling machines and tools, grindstones and tool grinding, the setting of slide valves and other subjects of interest to the practical machine shop man are discussed in a chapter devoted to each subject. The book should prove a valuable addition to the library of the shop man.

Applied Science for Metal-Workers. By W. H. Dooley, 467 pages, 5¼ in. by 7½ in., illustrated, bound in cloth. Published by the Ronald Press, New York.

This book is similar in character to *Applied Science for Wood-Workers* by the same author, and covers in the same way the general principles of science common to all industries. In addition to this it presents in an easily understood form practical applications of the principles underlying the metal workers' trades. It contains not only a presentation of the data necessary to equip the student for the intelligent study of industrial science, but also deals in a practical way with modern foundry practice, the making of wrought iron and steel, machine shop practice, sheet metals, structural steel and other subjects relating to the metal working trades. A series of questions and problems on each subject gives the student a very thorough examination and illustrates in a lucid manner the purpose of the work done as well as the methods used in performing it.

Proceedings of the Traveling Engineers' Association. Edited by W. O. Thompson, secretary. 366 pages, 5¼ in. by 8½ in., illustrated, bound in leather. Published by the association.

This volume contains the proceedings of the twenty-seventh annual convention of the association held at Chicago, Ill., September, 16-19, 1919. The address of the retiring president, H. F. Henson, is given in full. The reports of the secretary and the treasurer for the year ending July 31, 1919, are included and show the affairs of the association to be in prosperous condition. Committee reports and individual papers on various topics of interest to engineers and railway men in general are given in full with the discussion by the members. Among the subjects considered are: Methods for handling air brakes; adjusting tonnage of slow freight trains; advantages of the application of stockers to modern locomotives; locomotive efficiency and fuel economy; and caring for locomotives at terminals.

This volume also contains the obituaries of those members of the association who passed on during the year. Among these are Dr. Angus Sinclair and Dr. Walter V. Turner. The sketches of the careers of these two justly honored members of the Traveling Engineers' Association, together with an excellent likeness of each, will give this issue of the proceedings of the association an especial value to the members at large, as well as to a host of men in other walks of life.

METRIC STANDARDIZATION FAVORED.—Out of 58,226 petitions relating to exclusive use of metric weights and measures in the United States, now in the keeping of the Bureau of Standards, Department of Commerce, 57,800 petitions or 99.27 per cent favor this progress and only 426, or less than 1 per cent oppose it. This unqualified endorsement of metric standards for this country is brought out in the analysis just completed at Washington by representatives of the World Trade Club, of petitions sent to President Wilson and America's national legislators by prominent persons and powerful commercial, manufacturing, civic and fraternal organizations of the United States. Some of these petitions represent unanimous resolutions passed at conventions of organizations with thousands of members.—*Domestic Engineering.*

COMMUNICATIONS

OPEN THE SHOP DOORS

NEW YORK CITY.

TO THE EDITOR:

Did you ever stop to consider what this old world would be if we had not interchanged ideas in the past? What degree of progress would have ensued if everyone had had to make original discoveries of all that he utilized in his daily task? How much of that which you accomplish is due to knowledge acquired from others, from practices developed by others? Did you ever introspectively contemplate how your life, your occupation, and your success is dependent upon the dissemination of acquired knowledge?

Realizing these truths and the interdependence of mankind and industry, do you fully appreciate and utilize the avenues open to you for acquiring a small portion of the available knowledge and thus bettering your operating conditions. These avenues are: (1) Technical literature; (2) Technical journals; (3) Demonstrators, salesmen and service men; and (4) Personal observation.

Technical Literature. The most powerful agency today is the printed word. Records of past accomplishments can thus be used as stepping stones for better conditions and improved operation. Here are to be found the fundamental principles underlying all activities, as well as specific applications and a wealth of recorded knowledge.

Technical Journals. The technical journal supplies this same need but with a closer relationship to the specific task. Through it you are kept in touch with developments in advance of their availability in book form. Its many eyes and ears serve to keep you in close contact with the progress from which you can select that which can be most advantageously used without the necessity of saving to personally develop it yourself. Its advertising serves to bring to your door the wares of the world which can be used to increase efficiency, decrease costs and through better operation insure the very existence of your industry.

Demonstrators, Salesmen and Service Men. The developed efficiency of the locomotive of today and its parts such as the stoker, improved trucks, safety valves, automatic fire doors, superheaters, brick arches and numerous minor details has been brought about by the continued untiring efforts of the supply men. True the railroad man has done his share, but if it had not been for the supply man, his service and his energy, would the locomotive be what it is today?

While the relations with the so-called railroad supply man have been more or less close, it has not been so with the machine tool salesman and demonstrators. To them the average railroad shop has a closed door. The machine tool and small tool design manufacture and operation has developed much during the period that the railroads have marked time. Open the doors to the demonstrators, salesmen and service men. Don't turn them loose unguided in your shops, but consult them, let them aid you and you will be surprised at the knowledge acquired and the improvement effected through such contact.

Many concerns stand ready without expense to aid you in bettering your operation through demonstrators, but find it impossible to pass your closed doors. Don't, through fear of the exception who misuses the privilege of entering your shop, reject the good to be derived from the many who will amply repay you for the courtesy. Learn whether you are getting the best operation, whether your tools give the best and cheapest results. Don't blindfold your shop eyes by disregarding this service by the machine tool and small tool manufacturer.

Personal Observation. Go yourself to see what the other fellow is doing, but if you can't go send your subordinates. Go with the spirit of desire to learn and acquire, not to see in what you excel the other fellow. Human nature is such that it is easier to commend than to criticize. Observe with the intention of criticizing your own conditions, improving them and availing yourself of that which is done better elsewhere. Constructive criticism is a force; self complacent satisfaction is stagnation. If you would advance you must utilize the forces at your command and those of most value are the qualities of an open receptive mind and an open door. Open the doors of your shop to the agencies which instill competition and progress, and to the knowledge of others and the results will fully repay you.

G. W. ARMSTRONG.

REVERSING BRAKE SHOES A BAD PRACTICE

CHICAGO, ILL.

TO THE EDITOR:

In the December issue of your publication there appeared an article on brake shoe service, under the caption "Watch the Brake Shoes," which treats of a method of getting the most wear from the brake shoe and one that has been in practice for a number of years. You will, perhaps, be interested in my ideas on this subject and I should like to have them considered as a reply to the article mentioned:

The simple fact that there are still so many unevenly worn brake shoes on our cars today and still more evidence of them in our scrap piles would indicate that something is wrong with the practice of reversing worn brake shoes.

The practice itself has many objections. A brake shoe badly worn wedge-shape transmits torsional strain to the brake beam structure for which it was *not* designed. A turned brake shoe with the thick end at the top must have excessive slack in order to prevent its dragging too heavily on the wheel tread when brakes are released, which is very undesirable. With this slack in the brake rigging, the lower part of the shoe, which is thin, stands away from the wheel several inches. When the brakes are applied, the top of the shoe being in contact with the tread of the wheel, acts as a pivot and allows the lower thin end to slap against the wheel, often breaking the shoe. The position of a turned shoe with the thick portion at the top increases the pressure or drag on the wheels creating a still more severe retarding action on the wheels when cars are in motion and brakes released.

In the common method of applying brake beams the suspension is such that the forward end, plus the weight of the levers and rods, forces the top of the brake shoe against the wheel with a pressure of approximately 16 lb. per shoe. The natural result is a shoe worn thin at the top. If there is excessive slack in the rigging the top point of the shoe is worn. If the proper clearance only is provided, the shoe will wear gradually, resulting in the wedge shape so commonly seen.

Reversing brake shoes is not only a bad practice, which is eliminated by the use of a proper brake beam support, but the labor cost is greater than it should be. It is especially desirable to eliminate labor which is expended on bad practice. This class of labor that changes brake shoes is just as likely as not to change brake shoes that have already been changed. Duplicating labor in a bad practice is still worse.

In summing up the matter, isn't it a question of correcting the cause to get the proper effect?

By properly supporting the brake beam, we compensate for the force that is pressing the top of the shoe against the wheel, so that when the cars are in motion and the brakes released the shoes will not drag against the wheel. This will eliminate the unevenly worn brake shoe and do away with the necessity of careful watching and turning of the brake shoe.

Vice-President, Chicago Railway Equipment Company

LOCOMOTIVE OPERATION AND FUEL ECONOMY*

Quality of Fuel an Important Factor; Organization and Co-operation Effective in Preventing Waste

BY ROBERT COLLETT

Assistant Manager Fuel Conservation Section, Division of Operation

FUEL costs are a means for measuring progress. Good locomotive performance and good fuel performance are synonyms with good railroading, and it takes pretty nearly everybody on the railroad to bring it about. Three things are essential to real results—good fuel, good locomotives and real co-operation.

It is of interest to note the growth of the fuel problem. For the year 1912 the railroad fuel bill in the United States, for moving trains alone, was \$224,516,000. In 1918 it was \$495,612,000. Adding 12 per cent for fuel used for miscellaneous purposes, gives a total for 1912 of \$251,458,000, and for 1918 of \$555,085,000, an increase of 121 per cent. For 16 of the principal roads entering St. Louis the fuel bill for the year 1912, estimating 12 per cent of the total fuel as being used for miscellaneous purposes, was \$58,451,000; in 1918, \$149,602,000, an increase of 155 per cent.

In that period the number of locomotives in service on these 16 roads increased 9.9 per cent. The average tractive power of locomotives increased 7 per cent. The total freight business handled or gross ton miles increased 24 per cent and passenger car miles increased 4.5 per cent. In 1912 the number of superheater engines on these roads was 6 per cent of the total engines in service. In 1918 this had increased to 30 per cent of the total.

The majority of roads did not keep ton mile statistics in 1912, but for a few of the principal roads that did and which may be considered as an average, the unit basis of consumption decreased in the period of 1918 over 1912 in freight service $8\frac{1}{2}$ per cent per thousand gross ton miles, and in passenger service 8 per cent in pounds burned per passenger car mile, this notwithstanding the fact that the quality of the coal had deteriorated and that the very severe winter in 1918 was also a factor. It has been estimated for the year 1917 and for a considerable portion of 1918 the ash content and impurities in railroad fuel used in the United States increased at least 5 per cent. This is equivalent to 8,400,000 tons, or to 210,000 cars of 40 tons capacity loaded with incombustible material. This will serve to emphasize, if such emphasis were necessary, that although a greater efficiency was obtained on a unit basis the need still exists for securing the greatest efficiency from each locomotive in service and from each ton of coal purchased. It shows the greater penalty being paid for engine failures or poor performance, since the annual cost of fuel on the roads referred to increased from \$3,200 per locomotive in 1912 to \$7,450 in 1918.

The Fuel Situation

Prior to the beginning of the war the fuel question in many parts of the country could scarcely be considered a problem. Coal of the very best quality was so cheap that in some cases on busy coal-producing roads if a car were derailed it was cheaper to turn the contents down the bank than to salvage it. Slack and mill coal sold as low as 40 to 50 cents per ton and was sometimes dumped on the right of way for want of a market. Little wonder, then, that appeals to the enginemen and others for small savings were not always seriously considered. Sixteen million tons a year was the maximum exported, the larger part went to Canada. We are now told that some eighty million tons annually are required

for export and that Europe's reconstruction plan depends to a great extent on our ability to furnish fuel.

A few years ago Pocahontas and Westmoreland coal sold as low as \$1.25 per ton at the mines, or around \$2.25 at the seaboard; it is now selling as high as \$7 per ton at the seaboard for export and for ship bunkers. The ocean-going freight rate is from \$25 to \$30 per ton, and American coal recently bought by the city of Vienna at the present rate of exchange represents a cost to them of \$50 per ton. Even though the present miners' strike had not arisen, all indications are that with an average winter it is likely that the domestic, to say nothing of the foreign, requirements would not be met. The closing down of so-called non-essentials brings much discomfort and loss to the persons thrown out of employment. At the present rate of consumption each day there is from one million to a million and a quarter tons less coal in the United States. This means that the source of supply for railroad use is rapidly changing and that we must adapt ourselves to using the lower grades of fuel in order that the higher priced eastern coal may be available for ship bunkers and for export. Entirely apart, therefore, from a money-saving standpoint, the absolute need of every reasonable effort in the conservation of our fuel supply is apparent.

What Has Been and Is Being Done

Fuel is the second largest item of expense to the railroads. It ranks next to wages, and in the cost of train operation fuel costs not infrequently exceed that of wages. Fuel economy in railroad service has always received considerable attention, and fuel performance records are now compiled on all roads under federal control. The result is reflected in the saving shown on all roads in the nine months' period, January to September, 1919, compared with same period 1918, of \$21,863,990 in passenger and freight service, exclusive of company haul. On a basis of pounds used per switch locomotive mile there has not been a corresponding saving, due to the fact that with the reduced number of locomotives there has been a greater amount of work performed by each locomotive; compiled, however, on the volume of business handled or ton mile basis, switch engine saving amounts to \$2,716,500, bringing the total saving for the nine months' period to \$24,663,000. Very large economies have also been effected in power plants.

Fuel conservation has been ably supported, but while much has been accomplished much more remains to be done. Officers on individual railroads who have made ample study of the situation say that the surface has just been scratched.

Where Waste Occurs

At a meeting of representatives from each railroad in the Eastern region the question as to the causes of the greatest avoidable waste was asked. The substance of these replies were: Quality of fuel, locomotive conditions, delays at terminal and on the line, locomotive management, and the lack of the co-operation of all departments.

Quality of Fuel

Local environment usually decides the grade of fuel the railroad must use, but the most objectionable thing is to be continually changing the grades of fuel or the preparation of it. Coal containing more heat units or requiring different

*From a paper presented before the St. Louis Railway Club.

methods of firing or drafting of the locomotive from that ordinarily used, although giving excellent results on one division or railroad, may almost tie up another from steam failures. Buying for price or even chemical analysis on the open market should be avoided, if possible. The locomotive cannot be adjusted or the enginemen become accustomed to the change over night, and it is useless to expect it. Therefore, since the railroad must have its supply of fuel in order to move other business, less coal and fewer cars to handle it will be used if an adequate supply of uniform grade is maintained.

With contracts properly established with mines of known quality, good coal becomes a matter of proper organization and local supervision on the part of the mine operator reinforced by competent fuel inspectors employed by the railroad. A recent check of the number of railroad fuel inspectors indicates that, taken as a whole, for each two thousand dollars worth of fuel purchased less than one dollar is paid for inspection. To justify this expense it would require the coal inspector to effect an economy of only one pound out of each ton of coal purchased, or 1/20 of one per cent. Can we save this much with good coal versus bad coal?

A saving of 5 per cent, or 100 pounds per ton, is considered possible through better inspection alone. We have found coal being rejected by one road accepted by another road and placed

whose business will be to co-ordinate the ideas and efforts of the present railroad inspection force. In many cases the inspectors for a certain railroad can inspect for another road in the same section that does not maintain inspectors.

Locomotive Conditions

Waste from improper locomotive conditions includes, of course, special appliances which are put on either to save coal or to save work. It is not uncommon to find a modern locomotive with a superheater, power reverse gear and other fuel-saving devices burning from twenty-five to fifty per cent more coal, especially in passenger service, than a saturated engine in first-class condition, and such conditions often exist for long periods without being corrected. If there were some way to know what each locomotive burned each trip and this checked against the amount found by actual test to be required for a given service, it would be startling to know the waste of money that would be shown, and certainly it would not be allowed to go on. Locomotive design, adequate shop and roundhouse facilities are all important and are the foundation for good locomotives. I believe a small amount invested in a running shed at the principal shops where locomotives could be finished, after the "breaking-in" period, by the same shop forces who overhauled them, would be beneficial.

Relation of Coal Consumption to Weight of Trains in Freight Service

on the first road's locomotives at joint terminals. At one point 210 tons per day being loaded for commercial purposes required the services of nine slate pickers to remove impurities; but 900 tons per day from an identical seam were going for railroad use, with no slate pickers on the cars and all the impurities being loaded. Too much emphasis cannot be put on securing the best preparation the mine can produce and on intelligent distribution of the railroad fuel. Where possible, coal should be billed from the mines to the point where it is to be used and so carded that proper grades and sizes will be delivered; otherwise a car of coal is simply a car of coal to the yard men, regardless of kind of coal or equipment. The grade of fuel is the foundation of fuel economy, and mining conditions and miners' contracts have so changed in the past few years that it is just as necessary to build up the fuel inspection and distribution as it was to provide better inspection for pooled than for regularly assigned locomotives.

Recently a few regional fuel inspectors have been put on

A number of roads are getting excellent results from having traveling engineers ride locomotives the first trip from the shop. The defects are taken care of by the same force that overhauled the locomotive, and it is, of course, educational to them—the defects found being discussed in the shop superintendent's staff meeting. Locomotive failure records of roads using the same basis of comparison vary widely, from as low as five and six thousand miles per failure to as high as thirty thousand miles per failure. Aside from correct design, this is chiefly due to lack of attention to details.

We lack education in the care and handling of stokers and other appliances. In the matter of new types of power, European practices are, I believe, better than ours. They get one locomotive and test it out thoroughly, then build the others to that. We buy a large number of locomotives at one time, put them in the heaviest traffic territory, and the man who has to handle them is entirely unfamiliar with the types and, many times, the appliances.

Feed Water

Remarkable results have been accomplished on some roads in the improvement of feed water. On one road having something like 600 locomotives, where flues were formerly changed once in six months, fireboxes removed in from 12 to 18 months, the flues now run the full three-year period and the life of fireboxes increased correspondingly. This has been brought about by intelligent treatment of feed water, although the roads run through, for the most part, a territory which may be considered as bad-water districts from a scale standpoint. Where cost is not prohibitive and better water could be obtained, the source of supply has been changed. Where this was not possible, water treatment has been applied. The organization consists of a chief chemist, with one inspector for about 25 stations, or a total of 5 men for the entire railroad. On this road locomotive failures due to leaking flues were:

Before water treatment.....	1911—931 flue failures
After water treatment (not complete for all divisions), 1916—	34 flue failures
On the largest division (really two divisions).....	{ 1911—468 flue failures
	{ 1916— 1 flue failure

A record of staybolt renewals kept for 1916 showed:

One division without treatment.....	1916—196 per engine
Another division with treatment.....	1916—9.5 per engine

Fire box renewals were as follows:

	Fire boxes applied	Fire boxes per 100 locos.
Before treatment	83	14.1
After treatment	10	1.6

The cost of locomotive failures is difficult to estimate, but

six months or more, and often from shopping to shopping; others make renewals on an average of not more than eight or ten thousand miles.

It has been said that a locomotive new from the builders, having made its mileage and gone through the railroad company shop, should come out a better locomotive than the day it was received from the builders. Whether in pooled service or otherwise, the standard of maintenance of each locomotive should be such as a first-class engineer would have it if running it regularly and being fully supported by the shop forces.

Inspection methods differ widely, but we find that the roads making the best fuel performance give particular attention to this feature and also to the following up of locomotive failures. Inspection must go further than looking after broken frames, wheel flanges and loose nuts.

Delays

Certain roads have established standards of rating for movement at terminals and over divisions, for through freight trains, and check up each train daily. As an example, one division on a certain road, comparing with a similar period one year before, increased the train load $16\frac{2}{3}$ per cent, decreased the average time of the freight train on the road 32 per cent and decreased the fuel consumption 13.1 per cent. It is claimed that the influence of the chief train dispatcher was the moving spirit in this. Another road decreased the average time of freight trains at terminals 11 minutes each. On both of these roads these standards have been worked out from actual observation.

Hot boxes and equipment failures are responsible for a

In the Months of September in Four Successive Years

it has been stated on good authority that under existing conditions on a busy trunk line railroad \$100 per failure may be accepted as conservative.

Many tests have been made showing the fuel loss due to scale, but this represents the expense only partially. Some roads are renewing fireboxes at periods of 10 to 12 months and changing flues even more often.

Heating or lubricating failures waste fuel. Some roads have considerable trouble on this account, although the locomotives are liberally supplied with water pipes. On other roads operating the hardest service and certain trains not making stops over 150 to 180-mile divisions, with not a single locomotive on the railroad equipped with water, heating failures are almost unknown. This has been brought about by specializing at the shops and putting it up to the terminals.

Cylinder and Valve Blows

Some roads run cylinder packing on superheater engines

great waste of fuel and frequently for reducing the average tonnage rating in order that the average sustained speed will overcome such delays. One road has made great progress in this. The average miles per box in service is as follows:

	Total No. hot boxes	Miles run per box
Passenger:		
First nine months—1917.....	1,615	48,964
—1918.....	1,072	63,957
—1919.....	373	147,067
Freight:		
First nine months—1917.....	29,225	18,434
—1918.....	26,151	23,479
—1919.....	12,810	30,033

Their system is such that when a delay occurs or a car must be set out for a hot box they can put their finger, so to speak, on the individual at the terminal responsible for the hot box. But primarily it is due to good shop practice—terminal attention. Good authorities claim that the average cost of a hot box is not less than \$10, and when we consider the tonnage lost, wrecks, terminal-switching charges, wheel

changing, wages of men sent out, etc., we can readily admit that this is a conservative figure.

The gross revenue for one hundred-mile division for each 70-ton car of coal, the cheapest commodity we haul, is around \$45. Not infrequently a train sets out three or four loads over a division because of car equipment trouble or hot boxes. One reason for stressing these points is that the most of the fuel economy bulletins are addressed to engineers and firemen. They are only links in the co-operative chain, and no one knows so well as they do how often their best efforts toward economy are defeated.

Locomotive Management

This, of course, goes back to the early training of firemen and to capable supervision. The use of fuel combustion and instruction cars and of special men with no other duties than that of employing and conducting examinations of firemen is being extended. Under certain conditions firemen are paid during the learning period.

The use of printed forms recording observations of road supervision is now in more general use. Some roads make a summary of such observations each month for the benefit of general officers, in order that they may know how supervisors are directing their efforts, and from these reports also the general condition of the locomotives may be noted. As to methods, there are a number of men on every division of every railroad that know the best way to fire and run each class of engine. Supervision is provided for the purpose of standardizing such methods. In my opinion some such standard form of report is necessary in order that general officers may know that the men who need instruction receive it. By a little study and care, very great reduction in fuel consumption can be and often is made.

A supervisory officer will ride with a crew with a tally counter, counting the number of scoops fired between given points. The fireman will say: "Had I known you were keeping a record I would have done better." We have, as a result of information furnished by supervisors, any number of records where a reduction of from 25 to 30 per cent or even more has been made just through the personal interest of the engine crew in their endeavor to demonstrate just what they could do. Road foremen of engines, fuel supervisors and traveling firemen in the Eastern region, carry a tally counter and hundreds of checks have been made. Many of these records are sent to roads all over the United States with the name of the crew and all of the data of the run.

Poor pumping, failure to regulate the cut-off at high speed, irregular adjustment of the lubricator, shutting superheater engines off at a high speed with valves in short travel, are the most prevalent wasteful practices. We know that these things should not be done, but the men often work under adverse conditions and sometimes are not instructed.

Heavy Firing

A case of heavy firing on a Pacific type locomotive on an 81-mile run with a six-car passenger train was brought to my attention. On the first trip which the traveling engineer rode the engine, 497 scoops of coal were burned, and on the second day, 435. With another fireman on the next trip, 405 scoops were burned, with the same train and an Atlantic type locomotive. A few days later after the fireman had been trying to see just how well he could do, the same locomotive with the same train burned 303 scoops, a reduction of 26 per cent and a reduction of 39 per cent over the Pacific type locomotive. In another case where one of the regional supervisors rode the locomotive—not a case of operation altogether, but largely due to the reverse gear creeping—an Atlantic type locomotive on a 55-mile run, burned 81 scoops of coal. A Pacific type on following day, with the same train and run with two additional slow-downs, burned 230 scoops of coal. While some of this fuel was burned on

account of slow-downs, 124 scoops, of coal were burned in the first half of the trip or 50 per cent more for one-half of the trip than the Atlantic type burned for the entire distance. You have but to ask any locomotive fireman with as much as six months experience if it requires more coal for some engineers in the same service than for others, and a similar inquiry to engineers as to whether certain firemen burn more coal than others, will oftentimes bring the reply, "That we might better pay some fellows for staying at home." This seems rather strong, perhaps, but it is facts that we are dealing with and not theory. However, these are exceptions but as before stated, it is for these exceptions that supervision is provided.

Minor Wastes

Large locomotives on light passenger trains waste an enormous amount of coal. A committee of the Air-Brake Association estimated that six million tons of coal annually are wasted by controllable air leaks. Each square foot of steam heat line or other radiation surface uncovered, wastes one ton of fuel per year. If each locomotive on the New York Central Lines popped for ten minutes per trip, it would waste \$144 per year and two scoops of coal wasted per trip through decks, at gangways or from overloaded tanks, would mean \$54,000 loss, or enough to buy a modern locomotive.

Organization

Many suggestions have been offered as to types of organization. Obviously, the thing to do is to have such plans and purposes as will secure on each road the maximum amount of enthusiastic support from the chief operating officer down. Much of the strength of any organization lies in the general good opinion of those having to live with it. The supervision for locomotive operation and fuel costs has not received the same relative amount of attention as other branches of service. In the transportation department, below the rank of general manager, there are general superintendents, superintendents, trainmasters, etc. The mechanical department is officered likewise, but in locomotive operation we usually find one road foreman of engines on each division reporting to the master mechanic or superintendent. It does the master mechanic or superintendent no injustice to say that in the majority of cases, not having received their training through a similar branch of service and being charged with many other details of operation, the barometer of results being trains on time in one case and engine failures and shop appropriation in another, they are not always fully able to judge as to whether the road foreman or the fuel supervisor is getting full results. There is need for more general supervision. In the first place the road foreman's time may be taken up with a great many other things than the principal that his position is created for. At most there is one man for an average of about 35 locomotives, and since a great deal of his time is not given to locomotive operation, it is fair to assume that the equivalent is more nearly a man for each 50 locomotives. At \$35,000 per engine (a conservative estimate) this makes a total of \$1,750,000 worth of machinery that he is responsible for between terminals and also for the proper use of \$372,000 worth of fuel annually.

There should be one general foreman reporting to the general manager or through the superintendent of motive power or other staff officer. He should have enough assistance to cover the job, whether working through the regular organization or with a special fuel economy staff of his own, but if he handles the work through the road foreman, there should be an adequate number of men—traveling firemen of fuel supervisors—who have nothing but locomotive operation and fuel to claim their attention and whom he can call on. Any man on the railroad, whether he be road foreman or otherwise, who is charged with the supervision of locomotive performance, should assume his full measure of responsibility. If the mechanical department is handling fuel economy, they,

of course, are responsible for calling attention to wastes in any other department and of keeping all the other departments interested.

Co-operation

In giving you these experiences I have tried to show something of the growing importance of the problem. The cost of fuel has increased tremendously and it will probably never be so cheap as now. Some practices, now more or less prevalent, the scope of which might be extended, improving thereby not only the locomotive service, but the railroad machine as a whole are worth mentioning:

First—Better railroad fuel through better inspection and closer co-operation between the mine operators and the railroads.

Second—Improved locomotive conditions by closer inspection, distribution and maintenance.

Third—Improved road and terminal movement by establishing standards of performance and following up of delays.

Fourth—More scientific locomotive operation through better educational methods, supervision and records.

The charts that accompany this paper will serve to illustrate the direct relation that the average gross tons per locomotive mile bears to the unit fuel consumption. A good fuel performance means successful train operation and the maximum per cent of potential tonnage movement. These charts show the close relation between the weight of the train and the pounds of fuel used to earn one dollar.

Discussion

H. C. Woodbridge (Supr. Fuel Conservation Section): I rode on a locomotive recently that had a power reverse gear on it that would stay put. One notch made a difference in the action, and it would stay where you put it. You must make a drive on the transportation department men; you must not stop with the trainmaster and the dispatcher, although, the dispatcher can save more fuel than several first-class firemen. One of the big railroads has ore trains running out of the Lake Erie ports; one of their heavy trains has a record of having stopped 22 times in 125 miles. That was an old record, and they decided that at least 12 of those 22 stops were unnecessary—and they have been eliminated. But do not stop with the dispatcher and the trainmen, or the superintendent, but go to the men at the top.

W. L. Robinson (Division M. M.; B. & O., Washington, D. C.): What has appealed to me most in Mr. Collett's paper was a matter that was passed over rather hurriedly, but it is something that I have made a considerable study of, and that is the matter of measuring the actual amount of coal that is used on the individual locomotive. I think that is the greatest opportunity for fuel saving that we have left.

J. W. Hardy (Fuel Supervisor of the Southwestern Regional District): I do not believe there was ever a time in the history of our country when it was as necessary to have the right kind of supervision as it is now. When men had regular engines, and used to come in and report their work, they gave their locomotives supervision that they do not get today. Their engines are now delivered far from the shop and the work report is sent in by someone else, so that there is not the personal contact that there used to be when the enginemen were personally acquainted with the men who did the work. That, in turn, calls for closer shop supervision. The shopmen do not do their work with the same interest that they did, even in pre-war times. Shorter hours contribute something to that; one man tears a job down, and another one finishes it; in fact, there are many things that require closer supervision. It has only been a few years that we have had locomotive inspectors; that work used to be done by the regular locomotive engineer, and was done much better than it is done by the ordinary locomotive

inspector, because the engineer is more interested in the result that he would obtain on the road than the man who just simply inspects the engine. The growing demand for better supervision cannot be emphasized too much.

We need better supervision of our stationary steam plants. While it is true that only about 12 per cent of the total fuel used is burned in the stationary plants, there is a great deal of it used very wastefully. The consumption of fuel always increases in the winter time, and when that increase takes place there is a corresponding increase in waste, so that it is very important for us to turn our attention to all the little leaks.

In addition to the coal used by American railroads, 5,000,000 barrels of oil are used annually. Oil is being used in greater quantities daily, especially in the Southwest, and this trouble with the coal miners is undoubtedly going to make additional demands upon the production of oil. So I just want to mention that there is waste in oil, just the same as there is in coal. Sometimes in locomotive operation, the loss is greater on oil than it is on coal.

I just made a trip over some of the oil burning lines in the Southwestern region; there are several things that I learned—small things—but they contribute a good deal to the waste of oil. The matter of the quality of sand used has a great deal to do with the results that you get, and the way it is used has a great deal to do with it. I mention this because I know some of you gentlemen in this meeting are interested in the oil question. Yesterday I received from the Texas Pacific one of the most complete instruction books on the use of oil in locomotives that ever came out in this country. It contains the combined oil knowledge and experience of men in the Southwest and in California who have been using oil in locomotives for several years, and it is gotten out in the form of an instruction book by the Texas Pacific.

E. Hartenstein (Genl. R. F. of E., C. & A.): We have six men in the road foreman's department, and we have made it our business in the last six or eight months to station ourselves at the terminals when locomotives are set out for service to give them a thorough inspection. If we find that any defect exists that would cause an excessive use of fuel the locomotives are sent back and are not permitted to go.

We do not do that very often before the roundhouse foreman aims to see that the locomotives are put out in better condition.

We assume the same authority with regard to continuing an engine in service that is exercised by the federal inspectors; if we do not exercise that authority, we have to explain why to the man above us.

Eugene McAuliffe: A survey of the actual results obtained during the first nine months of this year, and projecting the curve through to the end of the twelve months, shows that after making an arbitrary allowance of seventy-five cents per ton to cover the cost of haul on user's rails, that the reduction in the cost of fueling locomotives and stationary plants including miscellaneous railroad fuel consumption for this year, as compared with last year, calculated on the basis of pounds of coal per unit of service will exceed \$45,000,000. The expense of operating the Fuel Conservation Section is only a trifle over \$100,000 per year.

The fuel problem is a bigger one than the fuel bill to the railroad. The coal mines of this country today furnish you 38 per cent of your freight traffic—your freight tonnage. They give, in addition, a very material collateral tonnage, in the shape of in-bound machinery, timber, steel, rails, merchandise, and perhaps a measure of passenger traffic that is not small. The mining industry as a whole, both fuel and metal, furnishes the railroads of the United States 68 per cent of their freight traffic. So, from a revenue earning standpoint, there is room for a direct and compelling partnership between the railroad industry and the mining industry.

The job has grown beyond the locomotive engineers and

ex-locomotive engineers. It is a job now, just as it has been for some years past, but to a greater extent now, that belongs to the highest executive officers of the railroads. It is too big to be treated as a secondary proposition. The railroads today are paying an average of \$4.05 per ton for coal, excluding the item of haul on user's rails, which I estimate will not be less than 75 cents per ton. I predict that a further increase of perhaps one dollar per ton will be added to the existing mine price. That will add \$100,000,000 or \$150,000,000 more to the railroad's fuel bill annually—a further incentive to our railroad executives toward taking hold of this problem.

The railroads of this country do not yet know how to buy coal; they do not yet know how to inspect coal or how to receive coal; and while the proposition of how to use it is a tremendously compelling one, reforms in purchasing and inspection methods will, if made, prove of great value.

There is a direct relation between fuel economy and the average weight of train, and if you secure the highest possible advantage through fuel economy the weight of the train will take care of itself. The savings effected not only will be those which flow from the decreased volume of coal consumed, but will be perhaps exceeded along other lines, through the heavier weight of trains, and a general reduction in operating costs.

RAILROAD ADMINISTRATION NEWS

In General Order No. 65, dated December 10, Director General Hines says:

"Grievances affecting employees belonging to classes which are or will be included in national agreements, which have been, or may be, made between the United States Railroad Administration and employees' organizations will be handled as follows:

"(a) Grievances on railroads not having agreements with employees, which grievances occurred prior to the effective date of any national agreement, will be handled by railroad officials in the usual manner with the committees and officials of the organizations affected for final reference to the Director of Labor, as provided in Circular No. 3 of the Division of Labor. Grievances on railroads having agreements with employees, which grievance occurred prior to the effective date of any national agreement, will be handled by railroad officials in the usual manner with the committees and officials of the organizations with which the agreement was made, for final reference to railroad boards of adjustment, as provided in general orders creating such boards. Decisions made as the result of such reference will apply to the period antedating the effective date of such national agreement, and, from the effective date of that agreement, will be subject to any changes that are brought about by national agreement.

"(b) Grievances which occurred on the effective date of any national agreement, and subsequent thereto, will be handled by the committee of the organizations signatory to such national agreement for final reference to the appropriate railroad board of adjustment, except on roads where other organizations of employees have an agreement with the management for the same class of employees, in which case grievances will be handled under that agreement by the committees of the organization which holds the agreement for final reference to the Director of Labor, as provided in Circular No. 3 of the Division of Labor."

Foremen in Mechanical Department Classed as Officers

Because of the exceptional importance of the work of supervisory foremen in the mechanical departments, and the fact that economical and efficient shop operation depends so largely upon their efforts and co-operation, W. T. Tyler, director of the Division of Operation, has issued a circular letter to the regional directors stating that it is desired that their classification, working conditions and privileges be made definite and uniform.

To that end the director general directs that general foremen, roundhouse foremen, departmental foremen and assistants will be classified as officers and will be given consideration and advantages attaching to officers of similar rank in other departments, as follows:

(a) Reasonable period of time lost on account of sickness without loss of pay.

(b) Two days off each month for all salaried foremen whose tour of duty consists of seven days per week.

(c) Two weeks' vacation a year with pay for all salaried foremen who have acted as officials continuously for one year or more.

(d) Privilege of resigning instead of being shown as discharged or dismissed.

(e) When charged with an offense likely to result in dismissal, a hearing to be given by a superior officer other than the immediate superior, at which hearing the foreman in question may be represented or assisted by any other foreman whom he may select for that purpose.

(f) Card transportation to be granted to all salaried foremen, the extent of such transportation to be based on the general practice for other division officers and the importance of the position the foreman occupies.

The letter says: "It is not possible to lay down a definite seniority rule, because ability and merit are of paramount importance in this highly responsible work and, in any event, must govern, but where the ability and merit of two men are equal, the choice of positions on a division should, as far as practicable, be determined upon the basis of seniority. I am sure that the uniformity brought about by the above rules will result in more loyal and efficient service by the foremen affected and will reduce complaints to a minimum. Will you please take action to have this put in effect at once?"

ORDERS OF REGIONAL DIRECTORS

Incomplete Brakes on Gondola Cars.—Supplement 2 to Circular 201 of the Southwestern regional director states that 500 U. S. standard hopper cars, allocated to the Pere Marquette, built by the Ralston Steel Car Company, and numbered 13,000 to 13,499, were placed in service without sheave wheels on brake and hand brake pull rod. The circular instructs that, where these cars are found with sheave wheels omitted on the end of the hand brake rod, changes should be made at once, regardless of ownership.

Employment of Apprentices.—The Northwestern regional director, file 42-1-100, states that statistics show that while there are 42,193 journeymen in the mechanical departments of the railroads in this region there are only 1,880 apprentices, or a ratio of one apprentice to 22.44 journeymen. Under the national agreement 6,559 additional apprentices can be employed. The circular adds that diligent efforts should be made to obtain the full ratio of apprentices, and special attention should be given to see that they are thoroughly instructed in the various branches of the trade in order that properly trained mechanics may be provided for the future.

Freight Car Distribution.—Supplement 18 to Circular 70 of the Northwestern regional director contains the following instructions, which are intended to assist in meeting the increased demand for grain cars:

"Effective at once, arrange to give the repair of grain cars preference over other classes of equipment. Additional forces should be employed where they can be used to advantage. Report as of Saturday of each week the number of cars repaired and made fit for grain loading for the preceding week.

"Reports continue to reach me of grain cars used in other service where other equipment is suitable and available. Unless cars are being loaded directly into grain-producing territory, instructions should provide for the use of non-fit cars. From now on special attention must be given to supplying grain cars, particularly for the heavy corn crop, which now demands attention."

BOILER COMPOUNDS; THEIR NATURE AND USE

Chemical and Mechanical Agents Used to Prevent
or Remove Scale; Quantity Required and Cost

BY W. S. MAHLIE

THE question of treating boiler feed water has been one of the most neglected items in railroad operation. The problem of economy and efficiency looms up with greater importance each day. The saving of fuel, the cost of which is no small portion of the operating expenses, has been very forcibly impressed upon railroad men. Outside of actual wastes in poor coal, insufficient combustion, etc., one of the important factors of fuel conservation rests upon the quality of the boiler feed water. In addition to the loss of fuel due to untreated water, there is the cost of the locomotive being out of service, new flues and fireboxes, labor in caulking and washing boilers.

It is not intended in this article to convey the idea that all feed waters should be treated with boiler compounds. By far the most of them should be treated in a regular water treating plant. The cost of treating water by the regular plants and by boiler compounds should be carefully compared and the results obtained from these treatment should also be studied. Boiler compounds are not to be regarded as absolute cures for all boiler troubles. They seldom do more than lessen the bad water conditions, the extent of which depends upon the original water and, of course, the compound used.

It should be kept in mind that a steam boiler was made to furnish steam; not to treat water, consequently the boiler should be supplied with good water so that it can perform the duty which is required of it. A person would hardly drink typhoid germ laden water and then take medicine to prevent typhoid, but rather, would use a pure water which would not produce disease. So it is with boiler water, an ounce of prevention is worth a pound of cure.

Boiler compounds are of many different compositions, some good, some bad, some indifferent. Viewed with the eyes of the practical water purification man, they are regarded as "patent medicines." Like patent medicines they are much advertised and all sorts of good and bad testimonials are recorded following their use. All boilers are not alike, neither are all boiler waters. For this simple reason no compound can be developed which is a sure cure for all boiler troubles. Some may be good for one thing, some for another.

In view of the many compounds sold, I have undertaken in a general way to show their classes, possible reactions, and other data, and let the buyer of the compound judge for himself as to its merits.

Requirements of a Boiler Compound

A successful boiler compound must fill the following requirements: (1) It must make the water non-corrosive. (2) It must hold in suspension, or colloidal form, all of the salts which would give rise to an incrusting precipitate. (3) It must put the water in such a condition as to keep it from foaming or priming. (4) It must be a chemical or compound of such a nature that it can be safely stored and kept from deteriorating. (5) It must be of such a nature that it can be easily measured or weighed and applied. (6) Its cost must compare favorably with other methods of feed water treatment.

It is not known exactly when boiler compounds came into general use. We find that during the development of the oil fields, it was a common practice to put a small amount of crude oil in a boiler to remove scale. Around saw mills it was also a practice to dump saw dust into the boiler to loosen scale. Thirty years ago bran was used in engine tenders to prevent scale in the boilers. Soda ash was used as early as 1864. Thus it will be seen that the use of boiler compounds was more in the nature of an evolution than a discovery.

Purposes for Which Used

Compounds are generally used for either one or more of the three following purposes. (1) To remove and prevent scale. (2) To prevent corrosion. (3) To prevent foaming. Only compounds of the first and second kinds will be considered here because, strictly speaking, the third kind are not boiler compounds, but anti-foaming compounds.

Classification

The boiler compounds may be roughly divided into three classes. (1) According to chemical action. (2) According to mechanical action. (3) According to combined chemical and mechanical action. In the following discussion

the terms temporary hardness and permanent hardness will be used, denoting respectively the bicarbonates of lime and magnesia; and the sulphates, chlorides and nitrates of lime and magnesia. The term incrustants is usually applied to the latter, but most practical men prefer the term permanent hardness.

Class I. Chemical Action

Soda ash or *sodium carbonate* is used more than any other chemical and is the base for practically all boiler compounds. Soda ash usually runs about 98 per cent pure sodium carbonate (Na_2CO_3). Another form known as soda crystals runs about 34 to 35 per cent (Na_2CO_3) the balance being water of crystallization.

The action of soda ash in the boiler is the same as in the regular treating plant outside the boiler. It removes the hard scale or permanent hardness, and neutralizes acids which cause corrosion. Soda ash was used in England as early as 1864. Too much soda ash should be guarded against as it will cause foaming when used in excess.

Sodium silicate or *water glass* is coming into extensive use as a boiler compound. It is seldom applied alone, but most always in combination with soda ash or tannin. Sodium silicate has the advantage of acting on both temporary and permanent hardness. When sodium silicate acts on temporary hardness one part of soda ash or sodium carbonate is liberated for each part of silicate added; this sodium carbonate is then available to act on permanent hardness.

In using sodium silicate the same precautions should be used as in all sodium compounds, since excesses cause foaming. Sodium silicate comes to the market in liquid form.

Sodium hydrate or *caustic soda* is not used as much as formerly and acts on both temporary and permanent hardness and neutralizes acids. Like sodium silicate in its action on temporary hardness each part of it liberates an equal amount of sodium carbonate available for action on the permanent hardness. Caustic soda is not available for removing sulphates of lime and magnesia alone, without the presence of enough temporary hardness, since by the action of caustic soda, hydrates of lime and magnesia are formed.

An excess of caustic soda is probably one of the worst things to get into a boiler, because like other soda salts it causes foaming, and has a decided action on brass valves and fittings. It also causes iron to become brittle when in concentrated solution. Caustic soda is bad material to handle, since it takes up water very readily from the air. It burns the skin and clothing, causing very painful sores, which are slow to heal. Caustic soda is sometimes mixed with soda ash and is known as Special Alkali. The approximate composition of this material is 40 per cent caustic soda and 60 per cent soda ash.

Tri-sodium phosphate was formerly used to a great extent, but is not used so much as present. It is distinctly a boiler compound since the reactions between lime and magnesia compounds are not complete at ordinary temperatures, but the water must be boiled in order to obtain the maximum effect. Like the silicate and hydrate of sodium in its action on temporary hardness it liberates an equal part of sodium carbonate, which can be available for further action.

The di-sodium has also been used as a boiler compound. The precipitates of sludge obtained from the action of the phosphates are very light and flocculent, and are easy to blow out of the boiler. It is claimed by some that sodium phosphates are the most efficient boiler compounds in use. Sodium phosphate was used in England as early as 1879 under the name of Tripsa.

Sodium fluoride is also distinctly a boiler compound. Dr. Doremus patented the use of this chemical as a water softening reagent. One of the claims made for this material is that one-fourth of the theoretical amount required will produce a sludge which will not stick to tubes or the sides of

a boiler, and is very easy to blow out. Another advantage claimed is that in using this compound, no volatile materials escape with the steam. No records were to be found anywhere describing the actual success with this compound.

Sodium oxalate has been recommended for use to prevent scale, but no instances could be found where it had been used. The reaction would be upon both temporary and permanent hardness with the formation of equivalent amounts of sodium carbonate.

Sodium chromate can be used to precipitate lime compounds, temporary and permanent. Another peculiar property of chromates is that they render iron passive to corrosion.

Sodium borate or *borax* has been used to some extent as a boiler compound. Lime compounds are precipitated cold, as borates, but magnesia compounds are only precipitated under the heat of the boilers.

In all the preceding discussion, sodium compounds only have been considered. It should be remembered that potash compounds will act in a similar manner, but due to the high price of potash compounds they are not used for this purpose.

Barium salts. In many respects the barium compounds are the ideal boiler compounds, since no soluble alkaline salts are left in solution by their use. On the other hand their cost is much greater, due to the larger amounts required for reactions, and also to the increased cost per pound compared with an equal weight of sodium compounds. In addition barium salts are poisonous and consequently are not desired, even around boilers, where any one might accidentally drink some of the water. Barium salts are ideal for incrusto-corrosive waters having high sulphate content, which otherwise would cause foaming by treating with sodium compounds.

The principal form in which barium is used is the hydrate. The carbonate can be used, but it is said it is not in as extensive use as the hydrate. The aluminate of barium should be a very desirable theoretical treatment, since it would also entangle and precipitate mud and other materials in suspension. Barium hydrate acts on both temporary and permanent hardness and acids. The carbonate of barium is not used much as a boiler compound, but more as a softening reagent in proper chemical treatment tanks. It is also said that barium carbonate is not very satisfactory on magnesium waters.

Lime. It formerly was a favorite practice in the French navy to add just enough lime to boiler waters to make them slightly basic. The lime reacts on the free acids, temporary hardness and magnesium compounds. The introduction of lime, however, adds a very bad feature to the acid waters, inasmuch as it will give rise to an extremely hard scale, and the acid is only removed or neutralized at the expense of adding hard scale to the boiler.

The writer has known of one case in particular where the addition of lime to a boiler gave good results. It was during the spring when the periodical acid conditions prevailed in the Ohio river. The flues and fireboxes of locomotives using this water began to leak so badly, that as one boiler maker said, "they wouldn't hold shelled corn." A small amount of lime was placed in the tender of one of these locomotives and the leaking disappeared at once.

Lime comes to the market in two forms, the lump or quick lime, and the hydrated lime. The lump lime is usually the cheapest and an equal weight of it is more efficient than the hydrated lime, since the hydrated lime contains about 25 per cent of combined water. The lump lime, however, becomes air slaked on exposure to air, and is then useless for water softening, while the hydrated lime does not slake. Lump lime runs about 88 per cent pure. When only small amounts of lime are used, the hydrated is probably the best to use, since it can be stored and does not slake. Lime

acts on all free acids, on temporary hardness and on magnesium compounds.

Chalk or Powdered Limestone. The use of this was advocated by the celebrated French chemist LeChatelier. It was introduced to act on sulphate of iron, and to act mechanically by being incorporated with the precipitated calcium sulphate or hard scale. It is not known whether or not successful results were obtained by its use.

Tannin Compounds and Wood Extracts. Tannins are used as scale preventatives in boilers. They are distinctly boiler compounds, and precipitate lime and magnesium as a light bulky precipitate. Tannins are seldom used alone, usually combined with sodium carbonate, sodium hydrate or sodium silicate.

Tannins are obtained from a great many sources, some of them being hemlock bark, oak bark, Canaigre, Quebracho, Palmetto root, Catechu, Gallnuts, Sumac, Valonia and Divi-Divi.

When tannin is used it leaves a very light friable deposit which is easy to remove. It is claimed that tannins are among the safest and best materials to put into a boiler. Some persons object to tannin, claiming that it would cause corrosion. No cases of such action, however, have been brought to light. The different bark extracts are mixtures of tannin and other closely related materials which act in a manner similar to tannin.

According to De Le Coux when a tannin, either free or combined with sodium compounds, is added to water, quite a number of complex changes take place, and the resulting action is that the tannates, gallates, and hydrogallates are precipitated in a mixture.

Zinc and aluminum. Zinc or aluminum have been introduced into boilers to prevent corrosion. The theory is that zinc and aluminum having a higher solution pressure than iron, will go into solution instead of the iron. This practice of adding zinc was started in 1881. Zinc has been much used, and even today is found in some compounds.

Commander Lyons of the U. S. Navy in 1913 made some interesting experiments on the use of zinc, and found that corrosion was lessened to some extent for a few days, and that then the zinc became coated with an oxide and the electromotive character of the zinc changed, and that instead of the zinc being attacked the iron became attacked. As a result the use of zinc was discontinued and 3 per cent normal alkaline strength of soda ash was used, which gave excellent results.

Sugar, Molasses and Glycerine. It has been claimed that sugar, molasses and glycerine are good scale preventatives, that they dissolve the lime and magnesia salts and hold them in solution, thus preventing a deposit. A number of investigators have studied the action of sugar on lime salts, and found that the oxide is dissolved, and that carbonates and sulphates are little affected. Inasmuch as lime-oxide is not present in boiler water the use of sugar could hardly be recommended. A series of tests was made to determine the solubility of calcium carbonate. Solutions containing one per cent, five per cent and ten per cent of sugar were allowed to act on calcium carbonate, with continuous shaking for 1½ hours. Solutions of glycerine of the same strength were allowed to act in the same way. Identical solutions of sugar and of glycerine were also allowed to act on calcium carbonate by boiling under 18 lb. pressure for two hours. In all cases the solubility was very slight amounting only to traces.

Another series of tests was conducted in a similar manner using calcium sulphate in the different concentrations of sugar and glycerine. It was found that while there was quite an amount of the calcium sulphate dissolved, it did not exceed in any instance the amount normally soluble in water alone. These experiments prove the fallacy of using sugar and molasses as scale preventatives.

Class II. Mechanical Action

Clay. De La Coux says—"Clay is a fairly good scale preventer, but there is danger of clay working into the machinery." It would appear to be a rather peculiar proceeding to add clay to boiler water, because most boiler waters contain clay and other suspended material which it is desired to remove. Clay could have no chemical action, and if added in sufficient quantity to act mechanically it would be almost sure to deposit on tubes and sheets and cause mud burning.

Talc, powdered limestone or chalk, pumice and ground glass would all act in a manner similar to clay. No advantage can be seen in the use of any of these since they all are inert chemically and they are not of a nature which would appear to benefit scale by being incorporated with it.

Starch, glucose, dextrin, potatoes, slippery elm, artichokes. Any number of materials of a similar character have been proposed. Their action, if any, is entirely mechanical. It is claimed that these substances dissolve in the water and form a sort of gummy gelatinous coating around the grains of deposited scale and prevent them from sticking so tightly together.

Dextrine, starch and glucose are more frequently used as binders in boiler compounds to hold the different constituents together, either in the shape of a ball or a brick.

Ground hoofs and horns have been used to prevent scale. When boiled these would yield glucoses and gelatines which would act as before stated.

Oils. The addition of oil to a boiler for preventing scale has been practiced for a long time. The action of course is entirely mechanical. Several explanations as to the action have been made. Some say the oil "rots" the deposited scale. Others say the oil envelopes the precipitated scale and prevents it from sticking. Others say the oil is attracted to the hot tube, becomes overheated, and forms a tiny explosion, which breaks or knocks off the deposited scale.

The benefit of oil addition would appear to be questionable. Christie in his book, *Water Purification and Its Use in the Industries*, devotes an entire chapter to the subject of oil in feed water, and after describing a number of oil filters says, "The use of oil in boilers to loosen scale is a positive detriment." He further says, "If oil must be used it should be a mineral oil, since animal and vegetable oils will very likely break down, forming free fatty acids and cause corrosion.

The writer, personally, has seen a great many boiler tubes, very badly bagged or blistered, caused by oil in feed water accumulating in a spot and becoming locally overheated. After installation of oil filters the bagging was entirely eliminated. After such experience one would hardly recommend that oil be used in a boiler.

Fats. Fat either alone or mixed with other substances has been proposed and used. It was probably the intention to coat the inside of the boiler with a coating of grease to prevent the particles of scale from adhering to the inner surfaces. No cases have been found recorded where this was entirely satisfactory. It usually caused local overheating where the grease was applied and the hot flame came into contact with the tube. In Belgium the custom has been for some time to rub the inside of the boiler with a mixture of tallow and amorphous graphite.

Rosin and Tad. Rosin has been used in a manner similar to fats. When tar was used it was mixed with five parts of oil before being applied.

Graphite. Literature on the use of graphite as a boiler compound is very scanty. After a thorough search, numerous instances were found where graphite was used, but no record of the results obtained were shown.

Graphite cannot be used other than from a mechanical standpoint in removing scale, since it is inert at ordinary temperatures. The producers of graphite say graphite will

not act chemically, but when the scale is deposited the graphite intermingles with it and prevents it from becoming a compact mass, and keeps it soft and easy to blow out. They also say that the graphite will work through the accumulated scale to the tubes and shell of the boiler and loosen the deposited scale. It is doubtful whether the graphite will do this, but if the graphite were coated on the inside of a new boiler, it would prevent much scale from adhering to it.

W. A. Converse, in an address before the Railway Club of Pittsburgh, May 22, 1914, made the following statement: "It is an absolutely well known fact that there is no possible chemical reaction between graphite and any substance found in boiler feed waters. Any action that might possibly be brought about that might be considered beneficial would have to be of necessity mechanical. It is absolutely impossible for graphite to permeate through any formation in the way of scale of anything like ordinary density. You cannot force it through with a pressure of 60 will probably not permeate the scale in practice in the boiler.

"There is this possibility. If you could get into the lb. I know. If you cannot force it through that way, graphite boiler and with a brush or otherwise polish the interior of the boiler itself as is done on a stove with stove polish, it would possibly smooth the surface of the metal and therefore prevent for awhile the adhesion of the particles of scale. But try to do that on a wet surface and you will find you are up against a very difficult job. And when applied to dry metal, graphite does not last long in contact with water. Consequently it cannot last long in a practical way."

In an article in the Journal of Industrial and Engineering Chemistry, May, 1916, H. K. Benson and O. A. Hougen describe experiments at the University of Washington. They say, "Graphite has no effect in holding suspended matter."

Some time ago a piece of peculiar looking boiler scale or deposit which had been removed from a Stirling water tube boiler was shown to the writer. One of the flues had been burned and upon examination this piece of scale was found. The material was a very hard, black amorphous

From this analysis it would appear that, first a mixture of calcium sulphate, calcium carbonate, and magnesium hydroxide, with a small amount of silica had deposited in the usual manner. Then due to this sulphate deposit the tube became overheated at this point, not, however, to the maximum. This overheating resulted in a decomposition of the calcium sulphate as shown by the equation.

This SO₃ (sulphuric anhydride) then with the water formed an acid which attacked the iron and formed iron sulphate. This iron sulphate with more or less carbon dioxide, formed a deposit of iron hydrates and carbonate. As the deposit became larger the overheating became more pronounced and due to the graphite present, finally assumed very high temperatures. These high temperatures and the graphite reduced some of the iron, so that a mixture of ferrous and ferric oxides was formed, and it happened that they were present in just the proper amounts to form Fe₃O₄.

The temperature attained in this case must have been very high and it readily can be seen that it was very dangerous to operate this boiler. However, it is unlikely that another case like this would occur again, especially going to the extremes this one did. However, one can see the danger of having something in a boiler which is liable to deposit on the flues.

Another piece of boiler scale from a stationary engine boiler, which did not carry such a high pressure as the preceding one, was examined. This scale was grayish in color, very friable, and easy to remove from the boiler. Graphite could be seen permeating the scale throughout.

The analysis was as follows:

Water	0.14 per cent
*Ignition loss	18.76 per cent
Silica	3.52 per cent
Iron and alumina	1.38 per cent
Calcium oxide	39.46 per cent
Magnesium oxide	4.99 per cent
Sulphuric anhydride	31.94 per cent
Total	99.19 per cent

*The ignition loss contained about 1 per cent free graphite.

Careful inquiry showed that the scale formation in the

TABLE I
QUANTITY OF CHEMICALS REQUIRED TO ACT ON THE VARIOUS DETRIMENTAL SUBSTANCES IN WATER

To Act on One Part of	Lime, Ca O	Sodium carbonate, Na ₂ CO ₃	Caustic soda, Na OH	Tri-sodium phosphate, Na ₃ PO ₄ , 12 H ₂ O	Sodium silicate, Na ₂ SiO ₃	Sodium fluoride, Na F	Barium hydrate, Ba (OH) ₂ , 100 per cent	Barium carbonate, Ba CO ₃	Barium chloride, Ba Cl ₂ , 2 H ₂ O	Borax, Na ₂ B ₄ O ₇ , 10H ₂ O	Tannin, C ₁₄ H ₁₀ O ⁸
Calcium carbonate as bicarbonate, Ca CO ₃	.560	1.060	.800	2.530	1.220	.840	1.712	1.449	1.796	3.820	6.440
Calcium sulphate, Ca SO ₄786	.588	1.870	.897	.618	1.259	2.809	4.735
Calcium chloride, Ca Cl ₂962	.721	2.283	1.109	.756	1.544	3.441	5.802
Magnesium carbonate as bicarbonate, Mg CO ₃	.660	1.262	.952	3.015	1.452	1.000	2.032	7.667
Magnesium sulphate, Mg SO ₄	.467	.890	.667	2.111	1.017	.700	1.423	5.367
Magnesium chloride, Mg Cl ₂	1.124	.842	2.666	1.284	.884	1.800	6.779
Carbon dioxide, CO ₂	1.272	2.410	1.818	5.757	3.895
Sulphuric acid, H ₂ SO ₄571	1.080	.816	2.583	1.748
Hydrochloric acid, H Cl	1.534	2.904	1.096	6.931	1.671	2.443	2.700

Note.—This table is based upon 100 per cent pure materials. These chemicals are rarely over 100 per cent pure, consequently a proportionately larger amount must be used than is shown on the table.

looking mass. It was also attracted by a magnet. The analysis of the scale showed:

Graphite	None
Silica, SiO ₂	1.36 per cent
Magnesium oxide, MgO	3.66 per cent
Sulphuric anhydride, SO ₃	21.73 per cent
Calcium oxide, CaO	21.19 per cent
Metallic iron, Fe	50.65 per cent

Upon recalculation to the possible combinations the following remarkable combination appeared:

Silica	1.36 per cent
Magnesium oxide	3.66 per cent
Calcium sulphide	19.58 per cent
Calcium oxide	5.95 per cent
Ferroso-ferric oxide	69.95 per cent

boiler was not lessened, however, the scale was changed from a very hard character to a rather soft mushy one. The use of graphite was discontinued in this case as unsatisfactory. These and some other similar experiences have convinced the writer that graphite should never be placed in a boiler to stop corrosion or to prevent the formation of scale.

Class III. Chemical and Mechanical Action Combined

Under this head all kinds of mixtures of the materials described in the preceding pages are used. The following are some actual analyses of commercial boiler compounds:

(1) A bluish green liquid, having a strongly alkaline reaction:

Specific gravity	1.40 per cent
Sodium silicate	45.79 per cent
Copper sulphate	1.69 per cent
Iron and alumina.....	0.17 per cent
Water (by diff.).....	53.35 per cent

(2) A greenish yellow solid material, put up in sticks about 1 1/4 in. by 1 1/4 in. by 12 in.

Moisture at 105 deg. C.....	38.43 per cent
Organic material, presumably tannin and binding material	9.15 per cent
Sodium silicate	7.00 per cent
Alkaline chromate	6.45 per cent
Free metallic mercury.....	0.62 per cent
Sodium carbonate (by diff.).....	38.35 per cent

(3) Volatile—probably spent tan liquor.....	52.83 per cent
Organic—probably spent tan bark.....	15.31 per cent
Residue sodium carbonate.....	30.82 per cent
(4) Moisture	9.69 per cent

- (15) Pure graphitic iron and one to four per cent of zinc.
- (16) Glycerol 15 per cent solution
- Oleic acid 8 parts
- Petroleum 20 parts
- (17) Zinc and zinc alloys and leather
- (18) Benzine, lamp black, animal fat, lard or horse; and tallow.
- (19) Graphite 50 oz.
- Soda 30 oz.
- (20) "A pulverized carbonaceous material mixed and incorporated with a saline solution."
- (21) Sodium phosphate and tannin.
- (22) 1 qt. water.
- 3 lb. whitening.
- 1/2 lb. soda (caustic).
- 1/2 lb. soap powder.
- 1/4 lb. borax.
- (23) Sodium amalgam 15 per cent
- Tannin 10 per cent
- Kerosene 10 per cent
- Whale or seal oil to emulsify.
- Caustic soda 15 per cent
- Dextrin 25 per cent
- Sodium phosphate 15 per cent
- Water 10 per cent
- (24) C₁₀H₈ (naphthalene) in gasoline or naphtha or other light hydrocarbon oil.

TABLE III

COST OF CHEMICALS REQUIRED TO ACT ON ONE POUND OF EACH OF THE VARIOUS DETRIMENTAL SUBSTANCES IN WATER To Act on One Pound of

	Lime, Ca O, \$0.63 lb.	Sodium carbonate, Na ₂ CO ₃ , \$2.99 lb.	Caustic soda, Na OH, \$4.22 lb.	Tri-sodium phosphate, Na ₃ PO ₄ , 12 H ₂ O, \$4 lb.	Sodium fluoride, Na F, \$17 lb.	Barium hydrate, Ba (OH) ₂ , \$33.33 lb.	Barium carbonate, Ba CO ₃ , \$3.55 lb.	Barium chloride, Ba Cl ₂ , 2 H ₂ O, \$3.50 lb.	Borax, Na ₂ B ₄ O ₇ , 10 H ₂ O, \$8.25 lb.	Tannic acid, C ₁₄ H ₁₀ O ₆ , \$65 lb.
Calcium carbonate as bicarbonate, Ca CO ₃35	3.17	3.38	10.12	14.28	57.06	31.52	418.60
Calcium sulphate, Ca SO ₄	2.35	2.48	7.48	10.51	41.96	4.85	6.29	23.18	307.78
Calcium chloride, Ca Cl ₂	2.88	3.04	9.13	12.85	51.46	28.39	377.13
Magnesium carbonate as bicarbonate, Mg CO ₃42	3.77	4.02	12.06	17.00	67.72	498.36
Magnesium sulphate, Mg SO ₄29	2.66	2.81	8.44	11.90	47.43	5.50	7.13	349.16
Magnesium chloride, Mg Cl ₂	3.36	3.55	10.66	15.03	60.00	440.64
Carbon dioxide, CO ₂80	7.21	7.67	23.03	129.82
Sulphuric acid, H ₂ SO ₄36	3.23	3.44	10.33	57.99	6.73	8.72
Hydrochloric acid, HCl.....	.97	8.68	4.63	27.72	81.43	9.05

Under price per lb. on this table, the materials in Table II have been recalculated to 100 per cent purity basis. All prices are shown in cents. Sodium silicate is not shown on this table on account not being able to secure satisfactory data in regard to percentages of Na₂SiO₃ present.

Metallic aluminum	3.93 per cent
Inert material	71.63 per cent
Graphite	13.75 per cent
This material was claimed to be as follows:	
Aluminum	5 per cent
Graphite	87 per cent
Pumice	8 per cent
(5) Moisture	16.79 per cent
Sodium carbonate	50.72 per cent
Inert material	1.67 per cent
Graphite	9.35 per cent
Organic { Dextrin }	21.47 per cent
{ Binder }	

The following is a list of some patented boiler compounds:

- (1) 75 parts tri-sodium phosphate.
- 8 parts ammonium sulphate.
- 17 parts soda ash.
- (2) 6 parts zinc dust.
- 48 parts soda ash.
- 18 parts bark extract.
- 10 parts dextrin.
- 4 parts graphite.
- 14 parts water.
- (3) Sodium carbonate..... 64 per cent
- Tri-sodium phosphate 15 per cent
- Dextrin or starch..... 1 per cent
- Tannin compound 10 per cent
- (4) 70 parts di-sodium phosphate.
- 20 parts borax.
- 10 parts sodium carbonate.
- (5) 70 parts sodium phosphate.
- 20 parts borax.
- 19 parts calcium carbonate.
- (6) Soda ash..... 75 per cent
- Meco tannin extract..... 25 per cent
- (7) 2 parts H₂O (water).
- 1 part HCl (hydrochloric acid).
- 0.01 part Hg Cl₂ (bichloride of mercury).
- (8) "An alkaline hydroxide and catechu together with an organic substance containing much water, such as potatoes, are heated until reaction ensues."
- (9) Ninety-eight per cent amorphous graphite, with a neutral organic vehicle.
- (10) "A solution of saponin, a neutral vegetable oil, such as eucalyptus oil, a basic alkaline salt, and an inactive vegetable colloid preferably carrageen jelly."
- (11) Hog lard or horse fat..... 100 parts
- Pine soot or graphite..... 3-19 parts
- Benzine or a petroleum or mineral oil..... 1-5 parts
- (12) "A mixture of soap and acid, nitric and hydrochloric, fat, resin and petroleum oil."
- (13) Naphthalene in caustic soda, Glaubers Salt (Sodium Sulphate) in ammonia, calcined soda, alum and ultra marine."
- (14) "Hydrochloric acid and a solution of bromide in potassium bromide and water. Add a mixture of sodium sulphite, sodium carbonate, or bicarbonate to remove free acid and bromine."

(25) Animal or vegetable charcoal, coal or lampblack in combination with caustic soda or soda ash.

In the preceding tables the items shown are the important points that should be considered in the use of boiler compounds.

Before going into the use of a boiler compound on a large scale, the composition of the compound should be ascertained, and its value in removing the scale and acid materials should be determined. The cost of the compound should be compared with the cost of treatment with lime and soda ash

TABLE II

WHOLESALE PRICES OF CHEMICALS IN EFFECT JANUARY 1, 1919	
Lime, 88 per cent.....	\$11.05 ton
Soda ash, 98 per cent.....	58.60 ton
Caustic soda, 76 per cent Na ₂ O.....	4.15 cwt.
Sodium phosphate.....	.04 lb.
Sodium silicate, 49 deg. Baume.....	.02 lb.
Sodium fluoride.....	.17 lb.
Barium hydrate, 54 per cent.....	.18 lb.
Barium carbonate, 97 per cent.....	65.00 ton
Barium chloride.....	70.00 ton
Borax.....	.08 1/4 lb.
Tannic acid (commercial).....	.65 lb.

In all cases lowest quotations are given.

in a regular treating plant. The labor in applying the compound should also be compared with the labor of operating a regular treating plant.

It should also be remembered that when using a boiler compound, the only way in which the scale can be removed is by blowing down. Blowing down wastes water and steam which has been brought to boiler temperature at the expense of coal.

NO BOLSHIEVISM THERE.—Railwaymen in Southern Italy sent a telegram to the prime minister offering to give the state an additional hour's work a day in order to increase the country's production.—Great Western Railway Magazine.

SCIENTIFIC DEVELOPMENT OF THE LOCOMOTIVE*

Factors Affecting the Cost of Maintenance and Operation Analyzed and Improvements Suggested

By JOHN E. MUHLFELD

MARKED progress has been made in the development of the steam locomotive as the result of superior engineering ability, and the results have in many respects been exceedingly effective. This progress, however, has been confined largely to an increase in size, weight, evaporating capacity and hauling power, and while the general use of superheaters and firebox baffle walls during the past ten years has substantially assisted in improving sustained boiler capacity and increasing thermal efficiency as well as in keeping the steam locomotive in advance of the electric locomotive, the opportunity for further improvement in thermal and machine efficiency and to reduce smoke, cinders, sparks and noise is untold.

The desiderata in a steam locomotive may be summed up as: a reasonable first cost; maximum capacity for the service within roadway weight, curvature and clearance requirements; ability to handle the heaviest gross tonnage practicable at the highest permissible speed; positive control of mechanical operation; economy as regards fuel and water consumption and repairs; minimum manual labor for road and terminal handling; construction of the least number of parts, and capacity to perform continuous mileage without failure.

Modern types of steam locomotives fulfill quite satisfactorily all of these requirements, with the exception of wastefulness in fuel, water and steam consumption, as may be gathered from the fact that the thermal efficiencies now obtained are only from 50 to 65 per cent at the boiler, from 60 to 75 per cent for the combined boiler and superheater, and from 4 to 6 per cent at the drawbar. These as compared with thermal efficiencies of from 3 to 5 per cent at the drawbar of an electric locomotive, 18 to 19 per cent at the switchboard of a modern

steam-electric central power station, 25 to 30 per cent for internal-combustion engines, and 40 to 45 per cent as claimed for the full range of from one-quarter to full load for combination internal-combustion and steam motors.

The increase in the first cost and in the cost for labor, fuel, material and supplies for operation and maintenance of the steam locomotive has been most marked during the past ten years, particularly since the war. It is now being operated and maintained by highly paid enginemen and mechanics, with high-priced materials and supplies, and the machine and its performance must be brought up to a more respectable basis of engineering efficiency if it is to be perpetuated.

The supporting data of this paper, which apply to the United States, present the reasons why the general improvement of the steam locomotive should embrace the following changes which are now being embodied in the construction of a new type of locomotive, the first of which it is planned

to have in regular service in 1920: *a*, steam at a pressure of about 350 lb. to be employed, superheated about 300 deg. F.; *b*, improved boiler, furnace and front-end design and appliances; *c*, greater percentage of adhesive to total weight, and a lower factor of adhesion; *d*, more efficient

methods of combustion; *e*, use of exhaust steam heater and flue-gas economizer for boiler feedwater; *f*, better steam distribution and utilization; *g*, reduced cylinder clearances and back pressure; *h*, lighter and properly balanced reciprocating and revolving parts; *i*, lower heat, frictional and wind-resistance losses; *j*, improved safety and time, fuel and labor-saving devices.

Reasons for Perpetuation of the Steam Locomotive

Much more has been said and written during the last few years about the electrification of the steam roads of the United States for the purpose of fuel and labor saving and conservation, but practically nothing has been set forth as to the possibilities to accomplish much greater results per dol-

Mr. Muhlfeld describes many radical innovations that are being incorporated in the design of a new freight locomotive and analyzes the defects of present types of construction.

*Abstract of a paper presented at the annual meeting of the American Society of Mechanical Engineers. Owing to the length of Mr. Muhlfeld's paper, it is not possible to publish it in full in this issue. The sections dealing with the generation and utilization of steam will appear in next month's issue.

lar of investment and operating cost by a scientific development of the steam locomotive. As the average use of power at any considerable load factor is for only 8 hours per day, and as there is more or less irregularity in the demand, due to the small use on Sundays and holidays, the available water power would be used only about 2,400 out of possible 8,760 hours per annum, or about 27 per cent of the time, so that the remaining 73 per cent would be wasted. Therefore, where continuous water power is available it should be diverted to the special requirements of large and regular amounts, such as in electro-chemical and metallurgical processes, in order that this waste may be reduced to a minimum.

The methods at present employed for generating electric power from fuel in large modern central power stations represent from 18 to 19 per cent thermal efficiency, and as the investment cost for a steam plant is from one-third to one-quarter of that for a water-power development, the same total investment would produce from three to four times as much power from a steam plant as could be secured from a hydroelectric plant.

Complete electrification of some portions of the large trans-continental trunk lines has been effected, all of which are representative of progressive engineering skill, but reliable reports and statistics available have not proven the actual operating economies predicted, and with the present unsettled state of the electrical art numerous objections present themselves, among which may be noted: *a*, prohibitive capital and non-productive cost per mile for road, equipment and facilities; *b*, non-interchangeable equipment adaptable to certain electric zones only; *c*, entire operation dependent upon single power plants and transmission systems; *d*, widely varying load factors—dependent upon business conditions—requiring enormous outlay to meet uncertain peak movement and emergency conditions; *e*, complication and congestion of road and terminal trackage with transmission and contact lines; *f*, first cost from five to ten times, and operating cost from two to three times that of steam; *g*, liability for complete tie-ups due to storms, snow, sleet, rain and short-circuits.

Any general plan to electrify the steam roads to meet other than terminal and trunk-line congestion conditions, at an absurd cost, would mean lack of efficiency and prohibitive financing, which would result in bankruptcy for most of the railroads affected and in a further burden upon the public. In fact, it would be a source of real danger to the rehabilitation of these transportation systems, as to discard steam locomotives where coal or oil is available and can be burned with efficiency, comfort and economy, represents absolute waste.

Proposed Order of Development of the Steam Locomotive

The opportunity for steam locomotives to produce economy by increasing train loads, reducing transportation and mechanical delays and saving fuel and labor, is enormous.

The principal parts of a steam locomotive assembly are the boiler, engine, running gear, tender and special appliances, and the functioning of these parts in operation, jointly or independently, will involve particular factors that are capable of scientific development, viz.:

- 1 Design, Material and Workmanship.
- 2 Adhesive Weight, Tractive Power and Factor of Adhesion.
- 3 Tracking, Curving and Riding.
- 4 Boiler Feedwater.
- 5 Boiler-Feedwater Purifying.
- 6 Fuel.
- 7 Combustion.
- 8 Boiler-Water Circulation.
- 9 Heat Radiation, Convection and Conduction.
- 10 Steam Generation.
- 11 Steam-Pressure Increase.
- 12 Steam Superheating.
- 13 Steam Distribution and Utilization.
- 14 Waste-Heat Distribution and Utilization.
- 15 Friction and Resistance.
- 16 Acceleration.
- 17 Deceleration.
- 18 Lubrication.
- 19 Insulation.

- 20 Safety Appliances.
- 21 Special Appliances.
- 22 Power for Accessories.
- 23 Time Saving.
- 24 Fuel Saving.
- 25 Labor Saving.

The supporting data relating to the improvement of these factors are presented below:

Design, Material and Workmanship

Only by greater refinement in construction can requisite operating results be produced to offset the increased cost of equipment supplies and labor. Therefore the designing should now be done along more scientific lines through the substitution of boiler, cylinder and drawbar horsepower and drawbar pull calculations for tractive power; thermal efficiency for evaporation results; distributed for centralized thrusts, strains and stresses; light, high-grade alloy and high-carbon steels and other metals for heavy, low-grade plates, forgings and castings; and in the more general use of high-grade engineering practice in lieu of rule-of-thumb methods.

In the modern high capacity locomotive it is necessary that certain parts be made as light as possible. On the other hand, the items of fatigue and shock of metals due to continued vibrations and impact as well as of inherent combinations of weakening chemical and physical characteristics, are responsible for many sudden failures of staybolts, plates, springs, axles, crankpins, tires, pistons and main rods, frames and like parts that are subject to reversal of stress or to hundreds of thousands of repeated and localized loads. As it has been found that the elastic limit is not necessarily representative of the fatigue strength, these factors require that further careful research and study be made for the purpose of determining upon a reliable quick test that will insure against unsuitable material entering into the construction.

The same degree of refinement applies equally to workmanship for construction and upkeep, which should be brought up to the same standard as obtains in other machinery that is producing more efficient and economical power for other modes of travel.

Adhesive Weight, Tractive Power and Factor of Adhesion

Adhesive Weight. In the ideal locomotive all of the weight is carried on the driving wheels for utilization as tractive power. The extended use of non-productive trailing wheels and the four-wheel leading truck has become an expensive fashion in that it has greatly reduced the percentage of total engine weight on drivers for adhesive purposes. For example, where a modern Mikado type locomotive will average 75 per cent adhesive to total engine weight, a modern Consolidation will run as high as 92 per cent, thereby utilizing much more of its weight to produce drawbar pull, hauling power and earning capacity.

Boiler design and weight distribution should be so correlated to the running gear as to make the use of trailer wheels unnecessary except where required by wheel load limitations, and with the more recent improvement in constant resistance leading truck designs any four-wheel arrangement, except for high-speed passenger service, should be entirely satisfactory.

Tractive Power. In calculating tractive power the usual practice is to use 85 per cent of the indicated boiler pressure in lb. per sq. in. for two and three-cylinder single expansion, and 52 per cent for two and four-cylinder compound engines. However, for a superheated steam locomotive the use of a higher percentage of the indicated boiler pressure should receive due consideration when making tonnage rating schedules before the train load is finally determined upon, as dynamometer tests have indicated that as high as 92 per cent for two-cylinder single expansion locomotives is permissible for train-loading purposes.

Factor of Adhesion. In the same way that the leading

and trailing truck type of locomotive has reduced the percentage of adhesive weight, so also has it increased the factor or ratio of adhesion, due to the "bridging effect" thus obtained over the driving wheels, tending to release the weight on the latter. Whereas many successful Consolidation types of locomotives are now operating with factors of adhesion of from 3.55 to 4.0, the Mikado types will usually range from 4.0 to 4.5. The co-efficient of static friction or adhesion between driving wheel tires and very dry, clean rails reaches a maximum of about 0.35, and for moist, muddy, greasy and frosty rails a minimum of from 0.15 to 0.20, giving factors ranging from 2.85 to 6.65.

In general, the factor of adhesion should be as low as practicable in order that the maximum power will always be available to start trains that can be easily handled when in motion and should about equal the ratio between the limiting friction in pounds and the weight on driving wheels in pounds, which for average dry rails is from 3.5 to 4.

Tracking, Curving and Riding

With the increased length, higher center of gravity, extended front and back overhang, and smaller proportion of spring-borne weight there have been many difficulties to overcome in order to maintain proper tracking, curving and riding qualities in locomotives of great power, and in the majority of cases these have been met with unusually satisfactory results.

Certain changes can be made, however, that will bring about a general betterment in the way of reduced rolling, oscillation, nosing and pounding, namely, reduced spread of cylinders; more uniform distribution and equalization of weight over driving and truck wheels; maximum permissible diameter of driving wheels; reduction in weight of revolving and reciprocating parts and counterbalance and proper distribution between wheels; improvement in constant-resistance lateral-motion devices; more uniform cylinder pressures when using steam and drifting; and greater refinement in control of end play, wheel and rail clearances, and tire-tread coning.

As the centrifugal power force of surplus counterbalance, the swinging movement of spring-borne weight and the rotative force on the crankpins are constantly changing in combination with speed and cut-off, the importance of giving particular attention to all of the foregoing cannot be overestimated.

Friction

Friction. Friction due to oscillation, concussion, rolling, wheel flanges and treads, journals, cylinders, valves, valve gear, crossheads, center and side bearings, coupler side play and the like absorbs a considerable percentage of the power developed by the steam.

Maximum machine efficiency, or ratio of drawbar to indicated horsepower, is usually obtained at speeds of from 25 to 50 miles per hour and ranges from 80 to 85 per cent, above which speeds, due to increased friction, it gradually decreases to about 70 per cent at 75 miles per hour. For example, with a locomotive developing about 2,000 hp. at a speed of 30 miles per hour, about 325 hp. would be lost in internal or machine friction.

During the past ten years the increased rigid wheelbase and axle loads, greater lateral rigidity, larger cylinders, valves and revolving and sliding bearings, substitution of grease for oil lubrication, and greater number of frictional parts, have tended to increase the machine friction and consequently the horsepower, drawbar pull, the steam and fuel losses.

All of these are factors that should receive proper consideration in new designs.

Resistance

Resistance. Other than the resistance resulting from machine friction, the locomotive is subject to those due to grades,

curves, weather, wind and head air, which latter is more particularly affected by the general design. As the horsepower required to overcome front air pressure increases with the cube of the speed plus the resistance due to the "air in motion," reduction of transverse flat surfaces, smoothing off of projections, vestibuling of openings and use of general curves parallel to the natural flow of the air should be carefully considered in high speed locomotives, particularly in view of the high fuel consumption and machine friction and the relatively small proportion of drawbar pull available for hauling trains at high velocities.

While the complicated design of a steam locomotive, particularly as regards the application of its accessories, makes the use of relatively smooth outside surfaces generally impracticable, still much has been done along this line on some of the European railroads that can be adopted by us to good advantage.

Acceleration

As the train resistance increases and the drawbar pull of the locomotive decreases due to speed, acceleration, rapidly becomes a diminishing quantity. Therefore in order to expedite train movement, locomotives should be designed and adjusted so as to permit of the highest possible rate of acceleration in the shortest distance after starting, in order that the maximum desired running speeds can be reached in the minimum of time during which the greatest evaporating capacity of the boiler is available. In locomotives designed with trailer wheels a great deal of otherwise available adhesive power, particularly for starting and acceleration purposes, is being wasted and the utilization of this lost adhesive weight by the elimination of trailer wheels, or by the application of an independent means of power for their propulsion, would accomplish a great deal in the way of starting and accelerating trains to speeds of from 15 to 20 miles per hour.

Deceleration

Deceleration is as much a factor in expediting train movements as acceleration, particularly with long and heavy trains and grades, and improved brake-shoe design, material, flexibility and bearing area in combination with clasp types of brakes for all wheels would do much toward providing greater stopping control over large and high speed steam locomotives and thereby avoid the necessity for resorting to the use of the engine cylinder back pressure to produce adequate braking power without liability for skidding and flat-tening the driving wheels.

Lubrication

Valve Oil. The usual method of feeding valve oil is through a steam-condensing lubricator. However, this method gives an irregular feed of oil to engine valves and cylinders if no change is made in the adjustment of the sight feeds when the locomotive is at rest, working with a light or a full throttle, or drifting. With high steam pressures and superheat a suitable automatic force- feed lubricator, located near the steam chests, with individual feeds to engine valves and cylinders and adjusted to insure a positive and uniform feed of 50 per cent of the oil to each of the valves and cylinders at all times when the locomotive is moving, will unquestionably give better results.

Piston and valve rods equipped with a suitable aluminum-zinc lead alloy metallic packing should not require lubricators or swabs except on roads where a high percentage of drifting obtains.

Superheat valve oil is unnecessary, as carbonization of oil is due to air admission to engine valve chests and cylinders when their temperature is greater than the finish point of the oil used and is also aggravated by the induction of gas and cinders through the exhaust nozzle.

The results of tests made to determine the respective co-efficients of friction of oil and grease-lubricated journals

show the former to be about 0.02 and the latter about 0.03. Therefore, while the internal or machine friction of the modern locomotive has been considerably increased due to the use of solid lubricants in combination with relatively high bearing pressures, and the wear on these frictional surfaces has been materially increased, grease has nevertheless protected bearings that would otherwise have heated, and its use will no doubt be continued until a satisfactory automatic force-feed method of oil lubrication is devised.

Machinery Oil. This is the ideal lubricant for wearing parts not subjected to excessive concentrated pressures and temperatures, and should be employed wherever a better distribution of the work, proportion of parts, or method of application will permit of its use. There is opportunity for much to be accomplished in the development of a more satisfactory and automatic means for its application.

Insulation

The loss of heat through radiation justifies a considerable expenditure for its prevention, and the most practical method for reducing this waste is to first design and locate the heat-transmitting parts so that they will be the least exposed to the surrounding atmosphere and to then make use of a good non-conducting lagging, properly applied.

With the available non-corrosive heat-insulating materials that can now be readily molded into sectional blocks to any form and size desired for ready application and removal, and which will withstand the disintegrating effects of heat, vibrations and concussions incident to modern locomotive operation, there is no good reason why boilers, fireboxes, steam pipes, valve chests, cylinders and heads, air pumps and other heat-radiating accessories or parts should be left exposed in the way they generally are, with the resultant steam and fuel losses.

Safety Appliances

While the annual reports of the Interstate Commerce Commission on personal injury accidents chargeable to locomotive equipment indicate that considerable remains to be done to improve safety with respect to boiler fireboxes, staybolts, flues, tubes, plugs, studs, blow-off cocks, water gages and grate shakers; injectors and connections; lubricators; squirt hose; reverse gears; main and side rods, and draft gear, a great deal in this direction has been accomplished during the past seven years through the co-operation of the railroads and the locomotive and equipment builders with the Interstate Commerce Commission inspectors.

Special Appliances

Tender Trucks. The present use of staggered instead of square rail joints in track laying results in considerable vibration and surging of tenders when first-class track surface and alignment are wanting. This derailing action necessitates the use of a flexible type of tender truck, such as will make it possible for each wheel to always follow and remain on the rail with which it is in contact without regard to any other wheel in the truck, if liability to derailment is to be avoided.

Truck Wheels. According to the reports of the Interstate Commerce Commission there were 954 derailments on the steam railroads during the year 1917 that were due to broken flanges and broken and burst wheels; these caused damage to railroad property amounting to \$1,132,030, and resulted in the killing of 16 and the injury of 72 persons. While these reports apply to both locomotives and cars, still they indicate the urgency for improvement.

With increasing wheel loads and speeds and higher and longer braking pressures the chilled-iron and cast and forged steel wheels must not only be of the best design, material and construction to meet the most severe requirements with a proper degree of safety, but the weights should be reduced to an economical maintenance and operating basis. Chilled iron and forged steel wheels have become particularly noto-

rious with respect to non-productive deadweight resulting from unsuitable or surplus metal, or both, and necessity will now demand an early betterment.

Mechanical Stokers. Reports indicate that stoker-fired locomotives burn from 10 to 40 per cent more coal than those hand fired, which includes the additional coal used for operating the stoker equipment, and that the cost for stoker repairs ranges from 2 to 4 cents per locomotive mile. Also that failures occur due to broken stoker parts, foreign matter in coal and wet coal. The kind and preparation of fuel are also items of importance, particularly as relating to low-volatile bituminous and anthracite coal.

It is doubtful whether any considerable progress in efficiency or economy will be made in the stoker firing of locomotives in combination with the limitations now imposed by burning coal on grates or in retorts with forced draft, and this is a matter of the greatest concern in the economic development of the steam locomotive.

Air Compressors. Compressed air is one of the most expensive mediums for producing power, particularly when the compressing is done by the single-stage system which is still in use on the majority of locomotives. As the steam is used at long cut-off and the heat of compression is dissipated and represents lost work, an average of from 70 to 85 lb. of saturated steam at 200 lb. pressure is required per 100 cu. ft. of free air compressed to from 100 to 130 lb. pressure.

For air pressures of 100 lb. and over a cross-compound steam and two-stage air compressor with intercooler between the air cylinders should be used. This will easily give an equivalent compressed-air production on from one-third to one-fourth of the steam consumption which results can be further improved by the use of superheated steam.

Main-Driving-Axle Boxes. These are the seat of one of the serious deficiencies in locomotives of great power. As any change in the alignment of the main driving axle or an accumulation of lost motion therein immediately affects the movement of the directly or indirectly connected main and inside rods, valves and pistons, it is most important that this axle be kept in close adjustment at all times. Increasing the length of driving boxes and the various means devised for applying and adjusting the crown bearings, hub plates and shoes and wedges have not yet produced the required result, and considerable opportunity for improvement still remains.

Lateral-Motion Devices. Restricting the lateral movement over leading and trailing truck and driving wheels as well as in tender trucks has been responsible for many derailments and much wheel-flange and rail resistance and wear, particularly with modern designs of locomotives of long wheel-base and high center of gravity. Promising results have obtained from the development of constant-resistance lateral-motion devices, but further improvement is needed along these same lines to meet the more extended rigid-wheelbase conditions.

Throttle Valves. These should be removed from the boiler where they are now an obstruction to making boiler inspections and are inaccessible for inspection, adjustments and repairs.

Power for Accessories

The steam locomotive must not only produce superheated steam for the development of drawbar pull, but also supply saturated steam to various accessories of its own and for train operation. Not only has the use of compressed air been found to be most expensive for the working of these accessories, but the reserve supply for train braking has been frequently drawn upon for their operation. As power reverse gears, fire doors, water scoops, coal pushers, ashpan doors and like devices can be equipped for steam operation, such substitution offers possibilities for less drain on the boiler and much needed economy in the cost for this auxiliary power production. Moreover, as all of this power for accessories is produced by saturated steam, some means for sub-

stituting the use of superheated-steam for those purposes where it is more suitable and economical should be given due consideration.

Time Saving

The principal time-saving factors other than speed reductions and stops necessary to take on and set off business and to meet roadway, train-despatching and operating requirements, may be stated as: *a*, acceleration; *b*, deceleration; *c*, mechanical road delays; *d*, mechanical terminal delays; *e*, fueling; *f*, watering.

Acceleration and Deceleration. Much time is to be gained in quickening the starting and stopping of locomotives. Any engineer who has noted the length of time usually taken to get a passenger, freight or switching locomotive, either light or loaded, under headway and to reduce the speed for a stop, will appreciate what this may amount to.

Mechanical Road Delays. These may be classed as due to engine, fuel, water and man causes.

With the adaptation of locomotives best suited for regional requirements and with proper improvements in design, material, construction, inspection, testing and upkeep, "engine causes" can practically be eliminated.

Through the installation of modern fuel-preparing facilities, provision for adequate tender capacity, adaptation of locomotives to utilize the most inferior and cheapest fuels available, use of simplified manual means of firing, and particularly by reducing the consumption required per boiler horsepower developed, the "fuel causes" can be substantially reduced.

The proper systems and time for washing out boilers and the supplying of suitable, treated if necessary, boiler water to adequate tender tanks will dispose of "water causes."

"Man causes" can best be avoided through the employment of competent men, the inauguration of proper systems for education and instruction, and by equipping locomotives so that they will require the least amount of arduous work.

Mechanical Terminal Delays. These are due principally to sanding, ashpan and fire cleaning, fire building, boiler washing, firebox, flue and smokebox cleaning, inspection, testing, machinery cleaning and repairs. Of these delays those due to ashpan, fire, firebox, flue and smokebox cleaning are the most prolonged and non-productive and can be reduced only by improved methods of firing, reduced fuel consumption per unit of work performed, and substitution of mechanical appliances for arduous labor, so that upon arrival at terminals locomotives can be run directly into the enginehouse instead of being held outside for this class of work and delaying upkeep attention.

Fueling. Many facilities for fueling locomotives, either with coal or oil, are obsolete, inadequate and uneconomical. Fuel should be prepared ready for firing before being placed on tenders, and with modern facilities practically no time should be lost in supplying, either on the road or at terminals.

Fuel Saving

The problem of locomotive fuel saving has never received more intelligent thought and attention from a supervising standpoint than during the past two years. This has been due to the war-time necessity for the conservation of both the fuel and the labor required for its production and to the fuel cost reflecting a constantly increasing percentage of the total expense for railroad operation.

While the furnishing of coal or oil of a proper kind and preparation) by an intelligent, trained and careful fireman to a locomotive in good working order and properly operated should result in effective and economical performance, the vast difference in the amount of fuel actually used by different train despatchers, engineers, firemen and locomotives to produce the same ton-mile movement under like transportation conditions indicates the necessity for reducing the amount of fuel to be fired per ton-mile by effective

mechanical means and methods instead of depending upon the directly involved and responsible human element for equivalent results.

There is no questioning the fact that avoidable low boiler and mean-effective cylinder pressures, saturated steam, indifferent boiler circulation, excessive firebox draft, clogged grates and boiler and superheated tubes, forced combustion, high smokebox temperatures, unnecessary non-adhesive weight and generally indifferent steam generation, distribution and utilization factors, for which the engineer and fireman are not responsible, have more to do with high fuel and water rates than those factors within their control. Therefore the proper procedure, particularly in view of the relatively small increase in cost for the improved locomotive equipment as compared with the total locomotive cost and the reduced expense for its upkeep and operation, is to design and equip the modern steam locomotive so that it will more fully utilize the thermal heat value of the fuel and not be so dependent upon the manual control to bring the fuel used for productive work within the proper limitations.

Making initial capital and continual upkeep and operating expenditures in order to provide well-known inefficient and uneconomical mechanical means for handling, firing and wasting greater quantities of fuel than are within the easy range of one-man hand firing, in preference to diverting an equivalent amount of money for capacity increasing and fuel and water-saving appliances, represents a policy that is not at all consistent with existing and future labor and fuel costs if the railroads are to be continued on an investment basis.

Labor Saving

The labor now required for the upkeep, terminal handling and operation of the steam locomotive is divided into three classes, i. e., shop and enginehouse men, hostlers, cleaners and supply men, and enginemen.

The item of maintenance is distributed between general and running inspection, testing and repairs and is taken care of at the shops and enginehouses, respectively. During the past fifteen years a great deal of attention has been given in the planning of these facilities to provide labor-saving tools and machinery for dismantling, repairing and assembling locomotives and appurtenances, and there are today many conspicuous examples of modern railroad shops and enginehouses, even though many more are needed.

Great progress has been made in the establishing of adequate and suitable terminal handling, cleaning and supplying facilities which now include power-operated coal, sand and ash handling plants and turntables, high capacity water cranes, hot water boiler washing and locomotive cleaning systems, steam and compressed air stack and flue blowers and similar appliances. The cleaning and dumping of fires, ashpans and front ends and the rebuilding of fires is, with the increasing size of locomotives and the use of inferior coal, becoming a matter of great concern, delay and expense in the terminal handling, particularly during congested traffic and cold-weather periods, and a satisfactory solution of this problem still remains to be provided.

In the operation of locomotives the hours of service law established the general practice of pooling locomotives and crews, which system until that time had been adopted by only a few of the railroads. The divorcing of the engineers and firemen from regularly assigned locomotives, in combination with the increasing size of the latter, resulted in relieving the enginemen of work which was transferred to the enginehouse forces. This change, in combination with the more extended use of power-operated auxiliaries, has practically eliminated arduous manual operation on locomotives of great power.

The mechanical requirements and status of the engineer and fireman on the large steam locomotive having been substantially changed, there should now be a resulting higher standard of operation, efficiency and economy.

A Five Car Train on the Manchester-Bury Line

ALL-METAL ELECTRIC MULTIPLE UNIT CARS

The Lancashire & Yorkshire, England, Built During the War Interesting Equipment for Its Manchester-Bury Line

BY ROBERT E. THAYER
European Editor of the Railway Mechanical Engineer

THE Lancashire & Yorkshire Railway was the first main line railway in Great Britain to adopt electric traction for its suburban steam service. Its first project was that of converting the Liverpool-Southport line, and later the

line was opened to traffic in March, 1904. The multiple unit system of train control was adopted for this line with two 150 hp. motors on each truck, operating at 600 volts direct current, the power generated being 3-phase, 25 cycles alternating current at 7,500 volts.

Interior of First Class Smoking Compartment

This electrification scheme has met with great success. Passenger business has been constantly on the increase ever since the line was put into operation. Whereas there were four lines required in certain parts of this electrified line for steam service, under electric service two lines are sufficient to handle the traffic, although the frequency of trains has been more than doubled. In this way the widening and laying of additional lines through an extensive territory, which would have been required had steam working been retained, has been eliminated.

On the Liverpool-Southport line, which extends to Crossens, there are 14 intermediate stations which lie at an average distance of less than one mile apart on the southernmost portion and are more widely separated on the northern portion. There were about 36 trains a day in each direction between Liverpool and Southport under steam operation. This number has been increased to 70 under electric operation. The total train mileage per day under steam operation was about 1,900. This has been increased to 3,500. The running time from Liverpool to Southport, which was 54 minutes under steam operation, has been decreased to 37 minutes. The express service between Liverpool and Southport has been increased from four trains per day to ten.

line from Sandhills Junction to Ormskirk, the two projects involving 38 miles of track with an equivalent of 80 miles of single track, including sidings. The Liverpool-Southport

During the first year of the electrification of this line 14 per cent more people were carried, with a reduction of from 78,393 tons to 69,160 tons in the total weight of rolling stock moved per day.

It was the excellent results obtained from this service that

lead to the electrification of the Manchester-Bury section of that same road, which was opened for service in February, 1916. This line runs from Manchester via Prestwich to Bury, and from thence to Holcombe Brook, which is $13\frac{1}{4}$ miles from Manchester. The line has rather heavy grades

line. As in the case of the Liverpool-Southport line, the number of trains on this new line has been greatly increased.

Profiting by the experience obtained on the Lancashire-Southport electrification, a new design of motor car and trailer was developed for this new project. On account of the heavy gradients, and further, to permit of as rapid acceleration as possible due to the large number of stations on the line, a careful study was made to make these cars as light as possible and still retain sufficient strength to meet

End View of Traller Car

with several grades over 1 per cent and three of 2 per cent or over. The heaviest grade is 2.4 per cent for a little less than a mile. There are 14 intermediate stations on this line between Manchester and Holcombe Brook. As in the case

Interior of Third Class Smoking Compartment

all service conditions. Whereas the Liverpool-Southport cars are built of wood and metal, the new cars are built entirely of metal, alloy steels and aluminum being used to a considerable extent in an endeavor to keep the weight down. By using aluminum instead of steel plate, the weight of the cars has been reduced 1,623 lb. These cars are the first all-metal cars to be built for main-line service in Great

Lancashire & Yorkshire Motor Car

of the Liverpool-Southport line, this line uses the multiple unit train control system, but the driving current is 1,200 volts direct current instead of 600, and the cars are equipped with four 200 hp. motors, as the grades on the Manchester-Bury line are much heavier than on the Liverpool-Southport

Britain. Forty-six of them were built three years ago at the railway shops of the Lancashire & Yorkshire with the same force of men that had previously been used in the construction of the wooden cars, and no difficulty was experienced in adapting these men to the new materials involved in the

construction of the all-metal cars. These cars are divided into three classes—the motor car, which is always third class and is provided with a baggage department, and first and third-class trailers.

Contrary to the usual British practice of compartment arrangement, these cars were built with the open aisle similar to American practice and in accordance with the design used on the Liverpool-Southport line. In commenting on this arrangement Sir John A. F. Aspinall (general manager of the road at the time the electrification was adopted) stated

doors are used, and, in fact, in the design of these cars the side framing has been calculated in as a supporting structure.

Comparison of Car Weights

The motor cars weigh unloaded 120,960 lb. These cars carry third-class passengers and have a baggage compartment. They have a seating capacity for 74 passengers, which gives a total unloaded weight per passenger seat of 1,634 lb. This compares with 2,206 lb., the weight per passenger of similar sized motor cars of composite construction.

Plan and Side Elevations of First Class Trailer Car

in his presidential address before the Institution of Mechanical Engineers that with this arrangement the trains can be handled at stations much more quickly than with the compartment coaches having the side doors. "The most crowded cars are always emptied during rush hours in about 50 seconds at terminal stations, while intermediate stops only require 15 seconds to pick up and set down passengers." He also said, in favor of this arrangement, that greater strength can be obtained with such construction than where the side

The third-class trailer cars, which are provided with motormen's compartments on each end, but which carry no baggage, have an unloaded weight of 64,960 lb. These have a seating capacity for 95 passengers, which gives an unloaded weight per passenger seat of 683.7 lb. The third-class cars are provided with seating space for five people across the car—that is, three passengers on one large seat on one side of the aisle and two passengers on the other.

In the table is given a comparison of the principal dimen-

sions of the all-metal cars with the composite cars in use on the Liverpool-Southport line and with the all-steel cars in use on the Long Island in the United States. Comparing these trailer cars with those in use on the Long Island Railway, it will be seen that, whereas the Long Island cars are practically the same length, they have a width inside the body of 9 ft. 4½ in. as compared with 8 ft. 11½ in. on

and first-class trailers gives an indication of this. In comparing the all-metal trailer cars with those in use on the Liverpool-Southport line, it is to be mentioned that the latter cars have a motorman's compartment on one end only and that the Manchester-Bury all-metal trailer cars have underframes of sufficient strength to permit of motor trucks being used. In addition, more brake work is included on the all-

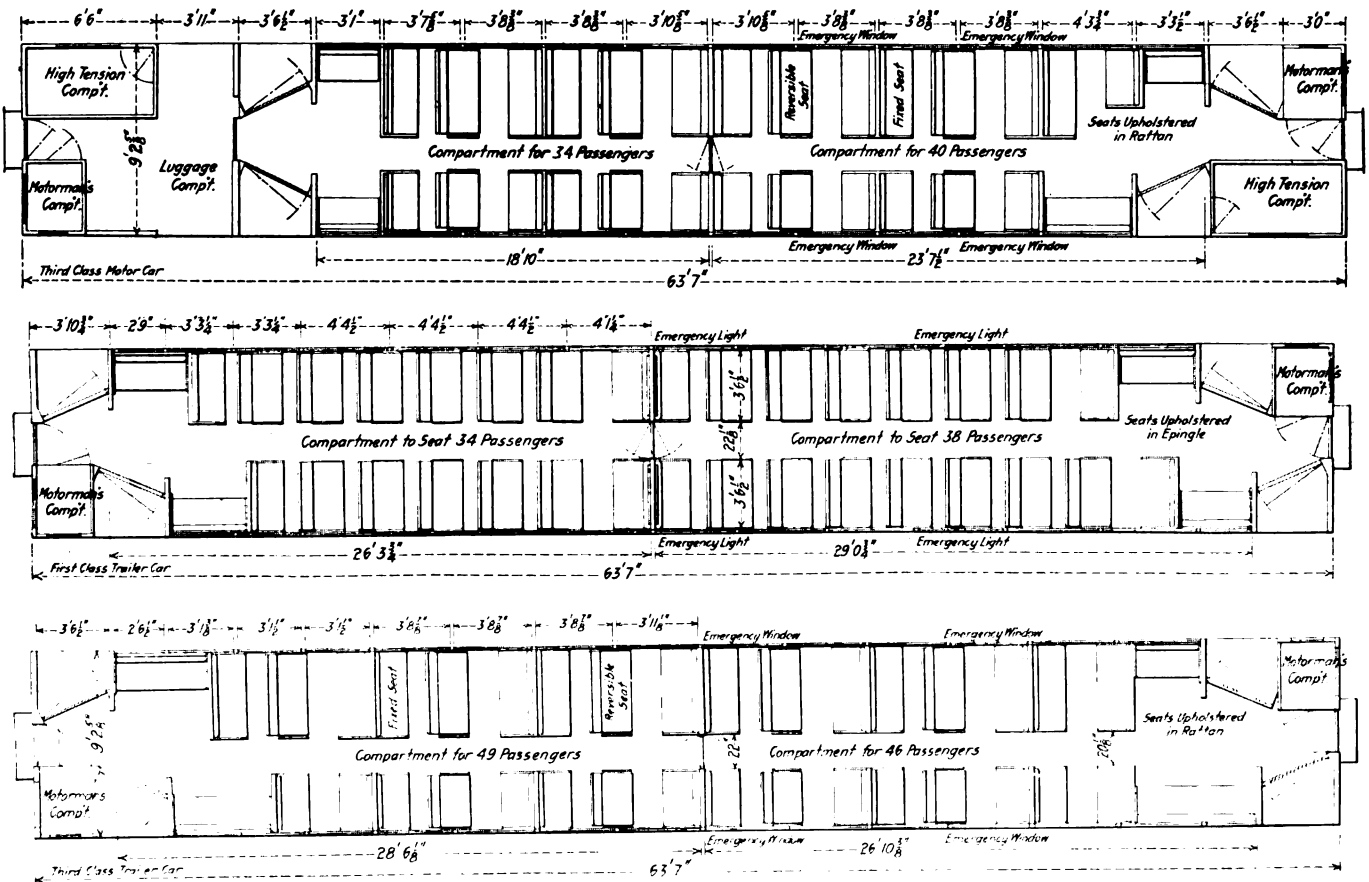

COMPARATIVE TABLE OF CAR DIMENSIONS

	Manchester-Bury M. U. C.	Liverpool-Southport M. U. C.	Long Island Trailer	Manchester-Bury Trailer	Liverpool-Southport Trailer
Length over all	63 ft. 7 in.	60 ft.	62 ft. 9¾ in.	63 ft. 7 in.	63 ft. 7 in.
Width over body	9 ft. 4 in.	10 ft.	9 ft. 9¾ in.	9 ft. 4 in.	10 ft.
Height of car inside, floor to roof	8 ft. 3¼ in.	8 ft. 0½ in.	8 ft. 3¼ in.	8 ft. 3¼ in.	8 ft. 3¼ in.
Height from rail to top of floor	4 ft. 1¼ in.	4 ft. 4¼ in.	4 ft. 4¾ in.	4 ft. 1¼ in.	4 ft. 4¼ in.
Height from rail to top of roof	12 ft. 4½ in.	12 ft. 7¾ in.	13 ft.	12 ft. 4½ in.	12 ft. 7¾ in.
Center of trucks	45 ft.	40 ft. 6 in.	39 ft. 9 in.	45 ft.	45 ft.
Wheelbase of trucks	9 ft.	8 ft.	6 ft. 4 in.	10 ft.	10 ft.
Type of roof	Clerestory	Clerestory	Elliptical	Elliptical
Number of passenger seats	74	68	80	95	97
Weight of two trucks complete	62,719 lb.	53,150 lb.	18,000 lb.	22,456 lb.	22,456 lb.
Weight of car unloaded	120,960 lb.	114,240 lb.	63,100 lb.	64,960 lb.	61,768 lb.
Weight per seat	1,634 lb.	1,680 lb.	788 lb.	683.7 lb.	636.7 lb.

the Lancashire & Yorkshire, and they have a seating capacity for 80 passengers as compared with 95 on the Lancashire & Yorkshire cars. The Long Island cars weigh 63,100 lb. or 1,860 lb. less than the Lancashire & Yorkshire cars, but on account of the seating capacity, due to the fact that the seats provide for only two passengers, the weight of the car per seat is higher, being 788 lb. as against 683.7 lb. for the Lancashire

metal cars. It has been calculated that these features account for 2,512 lb. of the total weight, which should be deducted when making a comparison. This would make the weight per passenger seat 643.7 lb. for the all-metal car, instead of 683 lb. as shown.

The make-up of the standard train which operates on the multiple unit control system consists of five cars, the leading,

Floor Plans of the Motor Car and First and Third Class Trailers

& Yorkshire. The width of the aisle in the third-class coaches with the three-passenger and two-passenger seats is 1 ft. 8½ in., and while that appears to be rather narrow, no great difficulty is experienced in passing down the car. Furthermore, the interior arrangement has been carefully studied and practically every inch has been utilized for seating capacity. A study of the floor plans of the motor, the third-class

center and rear cars being third-class motor cars and the intermediate vehicles first and third-class trailer cars.

Underframes

The underframe for the three types of cars, that is, the motor, the first and third-class cars, are substantially the same, having a length over end sills of 36 ft. 7 in. The

side sills are made up of 3½-in. by 10-in. by ¾-in. channels. The side sills, however, are further reinforced at the ends by a ½-in. plate riveted to the side sill, which extends

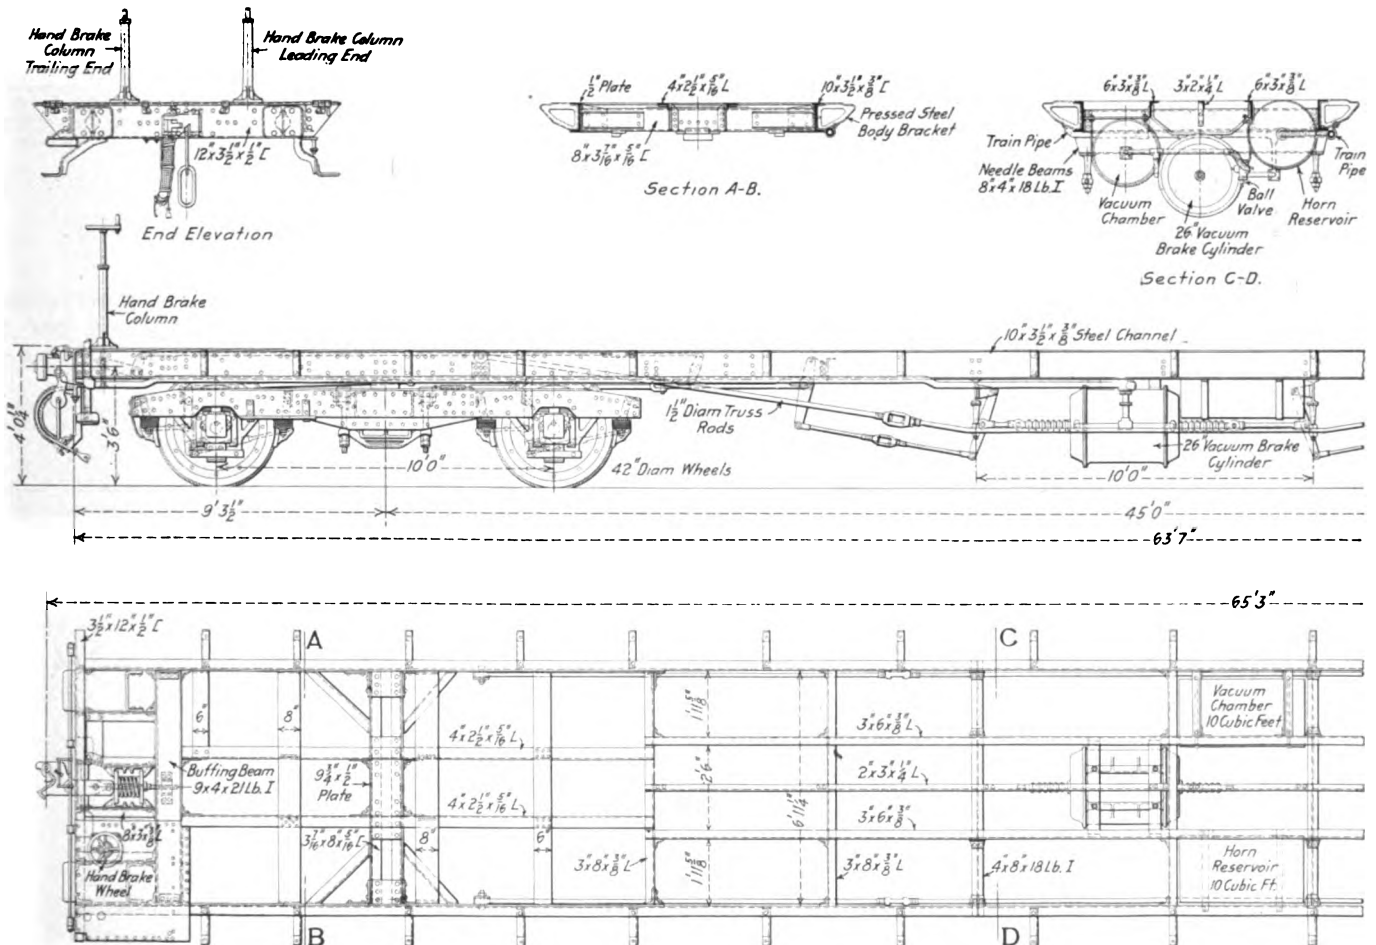

side of the center of the car. The end sills are 10-in. by 3½-in. channels. The body bolsters are built up of four 3½-in. by 8-in. angles, with ½-in. side plates and cover

Steel Underframe for the Motor Cars

17 ft. 5⅝ in. back of the end sill. The crossbearers are 3-in. by 8-in. alloy steel angles, and the intermediate floor sills are 3-in. by 6-in. by ¾-in. angles. These are set flush

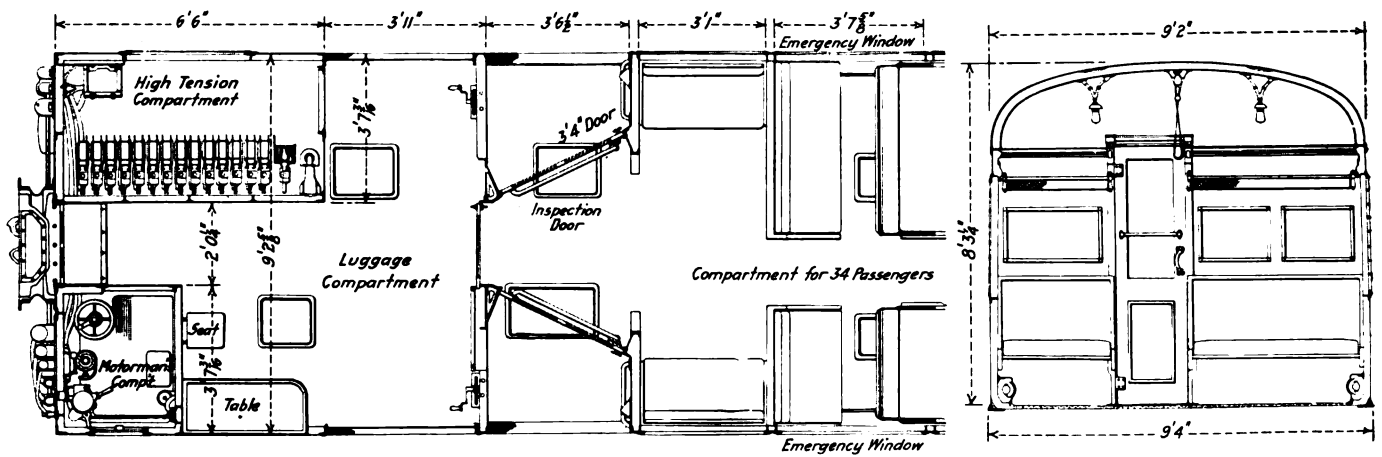

plates. They are attached to the side sills by steel pressings, and are further reinforced by pressed steel gusset plates. The draft gear is anchored in a 9-in. by 4-in. I-beam ex-

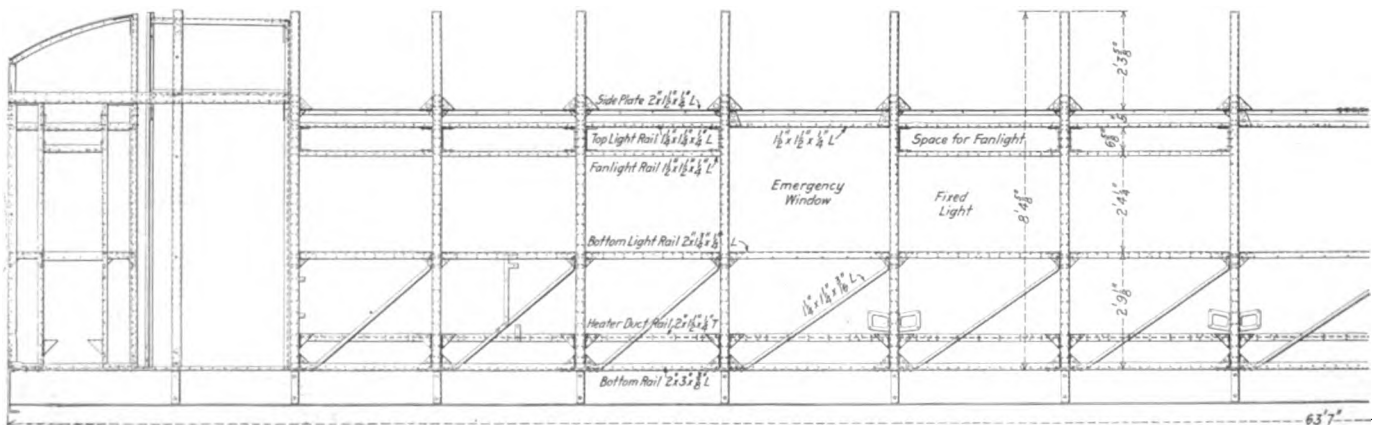

Steel Underframe for Third Class Trailer Car

with the top of the side sills and support the "Chanarch" flooring. The side sills are reinforced by 1½-in. truss rods which bear on 5-in. by 8-in. I-beams, located 5 ft. either

tending across the car between the side sills and located about 2 ft. 6 in. back of the end sills. This end construction is further strengthened by four intermediate angles ex-

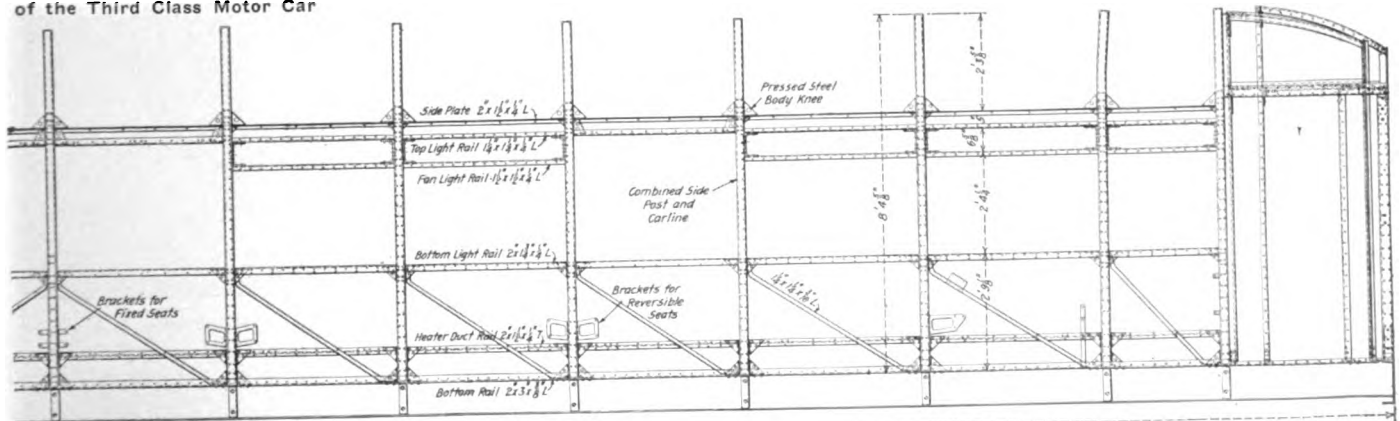

Side Elevation and Sections

End View.
of the Third Class Motor Car

Third Class Trailer Car

tending between the end sill and the I-beam, two of which are 3-in. by 3-in. and the other two 3-in. by 8-in. by $\frac{3}{8}$ -in. alloy steel angles. All of these angles have a side plate of $\frac{1}{2}$ -in. material.

The intermediate sills and crossbearers on the motor car are cut short just over the trucks in order to provide proper space for the motors.

The underframe for the first and third-class trailer cars

Trailer Car Underframe

are practically the same and are only different from the underframe of the motor car in that they have an additional intermediate sill made up of a 2-in. by 3-in. by $\frac{1}{4}$ -in. angles. They are also further strengthened over the trucks by cover plate strips and by two intermediate sills made up of 4-in. by 2 $\frac{1}{2}$ -in. by $\frac{5}{16}$ -in. angles.

Superstructure

The superstructure is designed to carry part of the load and acts as a continuous side girder to the underframe. It is made up of a bottom side 2-in. by 3-in. by $\frac{3}{8}$ -in. angle, which is riveted to pressed steel brackets extending out from

Interior View of Motor Car During Construction

the side sill of the underframe to which they are riveted. The side posts and carlines extend in one piece from the side sill to the ridge pole. They are 2 $\frac{1}{2}$ -in. by 1 $\frac{3}{4}$ -in. alloy-steel channels being bent and riveted to the side sill brackets at the bottom and united at the top by a plate riveted to the webs of the channel. They are equally spaced throughout the center of the car on 3-ft. 10 $\frac{7}{8}$ -in. centers. At the ends the spacing is a little closer together. They are braced by a belt rail of 2-in. by 1 $\frac{3}{4}$ -in. by $\frac{1}{4}$ -in. angles, located approximately 2 ft. 8 in. above the lower angle; by an upper

Equipment Beneath the Car Underframe

belt rail of 1 $\frac{1}{4}$ -in. by 1 $\frac{1}{4}$ -in. by $\frac{1}{4}$ -in. angle, and a side plate or cant rail of 2-in. by 1 $\frac{1}{2}$ -in. by $\frac{1}{4}$ -in. angle. In addition to this there are diagonal braces of 1 $\frac{1}{4}$ -in. by 1 $\frac{1}{4}$ -in. by $\frac{3}{16}$ -in. angles extending from the juncture of

the lower belt rail with the side posts to the 2-in. by 3-in. by $\frac{3}{8}$ -in. angle bottom side rails.

All the longitudinal rails are connected to the side posts by pressed steel knee plates. In addition to these longitudinal rails there extends along the lower part of the body structure a heater duct rail of 2-in. by $1\frac{1}{2}$ -in. by $\frac{1}{4}$ in. tee. There are other longitudinal rails extending between the side posts, which give the structure additional strength. The side and

ate the roof, and as the appearances do not require it no inner roof was used.

The sides of the cars below the windows are sheathed with No. 14 S. W. G. outside aluminum plates and No. 18 S. W. G. inside aluminum plates, with an air space of $1\frac{3}{4}$ in. between them. The inner sheathing was to improve the appearance of the car and also to serve as insulation. The side window frames are of aluminum and are riveted to the

Arrangement of Automatic Coupler and Draft Gear

roof plates are of aluminum. The roof sheets are made up of aluminum plates 12 ft. by 4 ft. $6\frac{1}{4}$ in. by No. 14 S. W. G. They are carried in one piece from side to side and are joined to the carlines with 2-in. by 1-in. strips of aluminum, which are well lagged and which are double riveted with $\frac{1}{4}$ -in. aluminum rivets spaced at a 3-in. pitch. In as much as the climate in which these cars are to be run is neither excessively cold nor excessively hot, it was unnecessary to insul-

side posts and rails with $\frac{1}{4}$ -in. aluminum rivets. The glass is embedded in felt and secured by a wrought iron frame secured to the main window frame.

As will be seen from the drawings showing the seating arrangements, some of the seats of the third-class cars are placed back to back. The outside ends of both the fixed and the reversible seats are supported on brackets riveted to the side posts.

Arrangement of Gangway Doorway

Truck Used on the Trailer Cars

Section Through Body Structure

Section D-D. Section C-C.

Doors

The arrangement of the doors is rather unique. In keeping with the all-metal construction of the car, these doors are of steel, having been furnished by Heywood Bros. & Wakefield Co. (United States). They are hinged on the inner door posts and arranged to swing outward, which greatly expedites the unloading of the cars. They are fitted

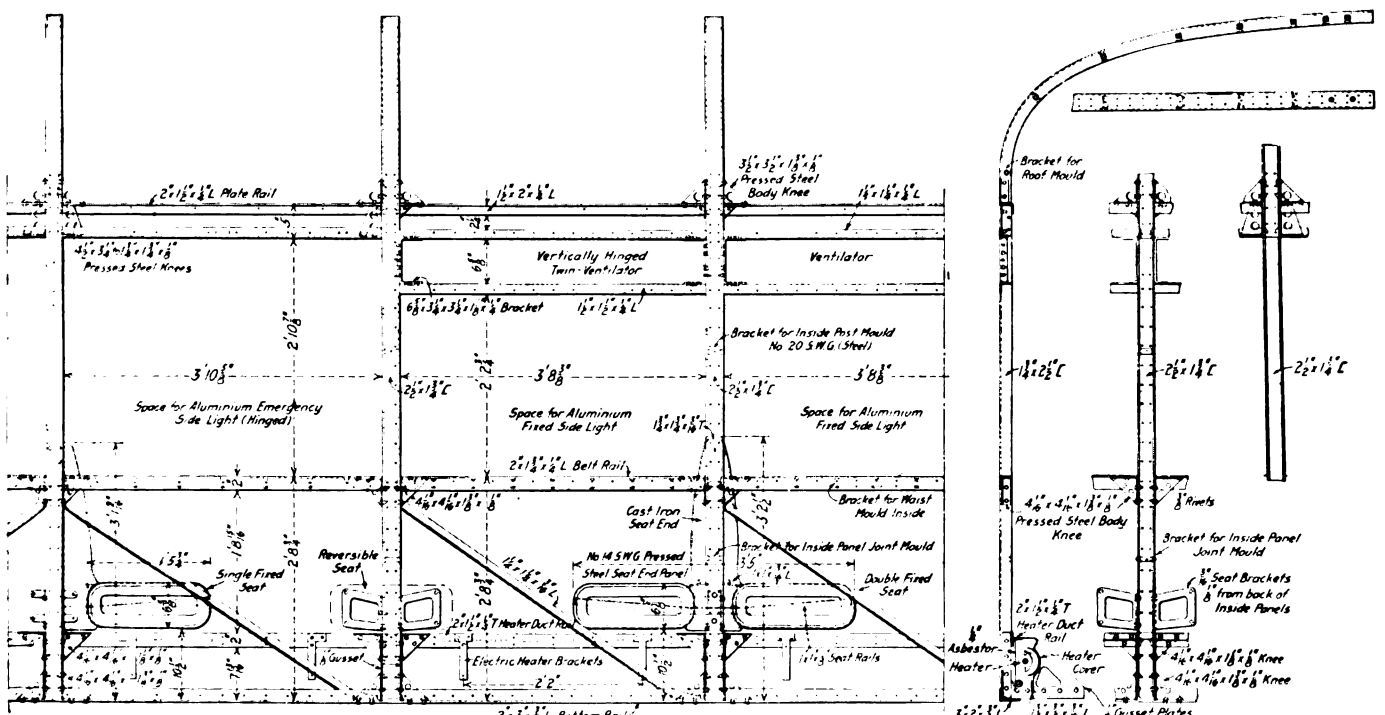

End Elevation of the Third Class Trailer Car

with an india-rubber welt in the door check to provide a water-tight joint and to eliminate any metallic sound when the door is closed. They weigh 141 lb. each, as compared to 114 lb. for oak doors.

Trucks

The trucks for the motor and trailer cars are of similar construction, those for the motor cars being built of heavier

Details of the Body Framing for the Motor Car

materials. Both are built up of structural steel, with box girder bolsters having a lateral swing of $1\frac{1}{2}$ in. in each direction. Four helical bolster springs are used, and semi-elliptical springs are used over each pedestal. The body framing of the motor truck is made up of 12-in. by 4-in. by $\frac{1}{2}$ -in. angles, being provided with heavy gusset plates

for the trailer trucks and 10 in. by 5 in. for the motor trucks. The driving gears for the motor trucks are pressed on to the axle, and in addition are bolted to the truck wheels in order to relieve the axle of severe torsional strains.

A gearing ratio of 2.36 to 1 is provided. The clasp type of brake is used on both trucks. The brake shoe is solid and of sufficient hardness to give a mileage of 8,000 miles.

Maintenance

In a paper before the Institute of Civil Engineers a short time ago both George Hughes, chief mechanical engineer, and F. E. Gobey, assistant carriage and wagon superintendent of the Lancashire & Yorkshire, discussed the question of maintenance of these cars. There have been in service for three years 46 of these all-metal cars. They have averaged 250,000 miles per annum and have operated in temperatures varying between 20 deg. F. and 120 deg. F. There has been no weakening since they were first placed into service

Trailer Car Truck

at the top. The truck bolsters are made up of 8-in. by 3-in. by $\frac{1}{2}$ -in. angles.

The trucks for the trailer cars have a body frame made up of 4-in. by 10-in. by $\frac{1}{2}$ -in. side angles and 3-in. by 6-in. by $\frac{1}{2}$ -in. end angles. The truck bolsters are built up of 9-in. by $3\frac{1}{2}$ -in. by $\frac{5}{8}$ -in. bulb angles, with 8-in. by

Rear End of Car, Showing Damage to Door in Collision

$3\frac{1}{2}$ -in. by $\frac{1}{2}$ -in. angles for the transoms. The side bearers are located 5 ft. 11 $\frac{9}{16}$ in. between centers.

The motor trucks have a wheel base of 9 ft., which gives ample room for the two 200 hp. motors. The trailer trucks have a wheel base of 10 ft. In both cases the diameter of the wheels is 42 in. and the journals are 9 in. by $4\frac{1}{4}$ in.

Showing Damage to Gangway in Collision

in any respect. The flooring composition has had no effect whatever on the floor sheets, but the original $\frac{3}{8}$ -in. thickness upon the top of the sheets is slightly worn in the aisles. It was found that aluminum oxidizes in contact with "Flexolith," and in this case aluminum has been replaced with brass.

The removal of the inside panels does not show that any corrosion or sweating has taken place on either body, framing or the inside of the outer panels. The actual car repairs in traffic have been slightly less than for wooden cars during a similar period. The all-metal cars are overhauled every two years, and it is expected that less material and labor will be required on them than for wooden cars.

The motors are given a general overhauling every six months, when the car body is removed from the motor trucks,

the motors taken out, the armature removed, the commutators examined, turned up and the mica undercut if necessary, the brush-gear overhauled, the armature windings cleaned, blown out and varnished, the field frame cleaned and connections examined, the motor trucks inspected, the wheels turned up if required and the bearings adjusted. Every 12 months the electrical equipment is overhauled. The average total number of faults per month for the 12 months ending July 31, 1918, was 72.4 and the faults per thousand motor-car miles was 0.78, of which the control equipment was responsible for 0.4 and the motor, motor trucks, cars and subsidiary equipment was responsible for 0.38, the largest of which was 0.13 for the subsidiary equipment. The reasons for the defects of the control equipment being so high was on account of the automatic control, which very largely increases the number of small parts.

In comparing the performance of the new all-metal cars with the cars of composite construction used on the Liverpool-Southport line, it is found that the faults per 1,000

motor-car miles was practically the same, being 0.76 on the Liverpool-Southport line as against 0.78 on the Manchester-Bury line. The greatest trouble in the Liverpool-Southport line was given by the motors, which average 0.26 faults per thousand motor-car miles.

The performance of the all-metal cars in collision has been demonstrated by three collisions that have taken place, in which it was found that the damage to the all-metal cars was confined to the ends of the cars. The doorways are the principal buckling points, which, being at the extreme ends of the cars and having vestibules, absorb the blow. The light car structures minimize the force of impact, and the effects of the collision where the metal framing is suitably disposed. There was no difficulty in carrying out the repairs in the car shops. The metal structure absorbs collision shocks in less space than the wooden cars, with the resultant effect that there is less liability of injury to passengers. Some illustrations are included to show the effect of collisions on these all-metal cars.

THE INSPECTION OF FREIGHT EQUIPMENT

The Defects that must be Avoided in the Selection of Freight Cars for Certain Commodities

BY L. K. SILLCOX

Master Car Builder, Chicago, Milwaukee & St. Paul

IN any successful movement of traffic it is of prime necessity to first see that cars going to industries, loading stations or loading territories beyond the reach of local car repair points are gone over and put in suitable condition to run to whatever destination they may be scheduled to reach; also that they are in fit shape to carry the lading which they are intended to carry, this to avoid delay in movement, damage claims or the necessity of transferring the load en route. For this reason large terminal loading tracks should be piped with air and have suitable repair materials and facilities conveniently placed. In the past entirely too little attention has been given equipment at loading platforms at large industries, when it has been a matter of daily experience to have cars brought right over at the close of the day and placed in our most important time freight trains, and then there was not time enough allowed to do the necessary work on the equipment, the latter being true since no effort had been made to put the cars in shape while they stood idle during the day. The result is obvious, and with the matter brought out so clearly and being one of daily observation we must make the necessary effort locally at every station on the system to correct this state of affairs at once. No one could possibly estimate the great and tremendously far-reaching effect of this and what good may result when this item is properly understood and uniformly applied.

A box car to handle grain, flour, sugar or groceries should be in the best condition possible. The siding must be tight, the roof non-leaking and the floor and lining level and smooth, so as not to chafe or injure the contents. Wool, raw cotton, hay, brick, etc., may be handled in a car in fair condition without damage. A leaky roof or open siding will not injure these articles, and they cannot fall through cracks in the floor as would bulk grain. The only essential for cars handling the last mentioned articles is that the frame work of the car be strong enough to hold the load and that the trucks and draft gear be in good condition.

A refrigerator car must always be in good condition in order to protect its lading, due to the fact that the require-

ments of this service are very rigid. A stock car should be in good condition in order to handle live stock without damage, but the same car in fair condition will haul barreled goods, rough lumber, ties, lump coal and many other articles very satisfactorily. A gondola must be in very good condition to hold slack coal without loss, but will hold lump coal, coke, scrap iron, etc., if in only fair condition. Trouble is experienced when we get out into the lignite coal district. If any old car is used for this coal loading, the car and contents are both liable to be burned up. A pretty good car must be used on account of the fire risk.

There are a good many commodities that should never be loaded in a first-class car, and this is one of the worst practices that is prevalent on railroads today—the abuse of good cars by loading certain commodities in them. For instance, hides, fertilizers, immigrant outfits, scrap iron, coal, pitch, oil, refuse from sugar factories, tar and things of that kind should never be put in a first-class car. This matter should receive more attention than it does at present. If we have around 75 per cent, or about three-quarters of the box cars in first-class condition we ought to be able to take care of our business in a satisfactory manner. By first-class condition is meant a car that is good enough to handle grain or similar products.

In order to define the requirements of cars for various commodity loading the following will govern:

Grain Cars

A suitable car for bulk grain loading is one that has the decking, lining, sheathing, posts and grain strips and roof in a good, tight condition, or in other words, *will not leak grain*, or a car which can be made fit by the shipper at the time and place of loading by ordinary and proper care in the use of coopering material and by a reasonable amount of cleaning. A car with doorposts shattered or broken or loose from the framing, or with other defects of such character as to render the car obviously unfit, or with the inside showing the presence of oil, creosote, fertilizer, manure or other damaging substance of like or kindred character should not be used for grain. Where a shortage of suitable cars ob-

tains, it is often desirable and necessary to fit cars up especially, and under these circumstances, where the body of the equipment can be made fit and suitable in 20 carman-hours or less, it should be done. This work is usually carried out under extreme pressure and may consist of employing anchor bolts to secure door posts, slabbing the sheathing at both the end and sides to sills, reinforcing broken posts with old iron, such as levers, threshold plates, iron scraps and applying a supplementary end lining over the old or defective structure, including false bulkheads in the body of cars, jacking bulged out ends in place and applying straps, anchor rods or bars, slabbing side or end plates, slabbing belt rails, patching sheathing, roofing and floors with old metal roofing. Under all circumstances the running gear, brakes, wheels, lubrication and safety appliances must be in as nearly 100 per cent condition as possible. All of the above is exclusive of applying grain doors, as these are installed by the shipper. In delivering empty cars suitable for grain loading to our connections, it shall be the understanding that the cars which cannot be made fit with the expenditure of ten carman-hours shall be returned, the same to be true as a basis of acceptance between connecting lines giving us care for such loading and ourselves. In further explanation, box cars which are fit, or such as have light running defects, will be accepted or offered on an equal basis. In order that there may be a universal understanding as to what is meant by the term "light running repairs," it will be understood that this covers cars having such defects as missing plain wooden side doors (this not to include Wagner or other special all-metal or steel-bound side doors), broken draft timber or strap bolts, slight defects to wooden or metal roofs, to side or end sheathing and lining, or other light running repairs such as can be made by the receiving line on division or yard repair tracks within the time allowance prescribed, or such as can be coopered by the loader to make the body fit for the lading intended.

Flour Cars

In going over cars for flour loading, the main points to be considered are a good, tight roof and sides, good, close-fitting doors, a good, clean floor and freedom from the presence of oil, creosote, fertilizers, manure or acid spots which are liable to contaminate the lading. Roofs to be given water test where possible. A car that has been loaded with hides should not be used for flour, or any other car that has been loaded with commodities which have left a bad odor. During the winter months cars equipped with all-metal roofs or ends uninsulated should not be selected for flour loading unless it is distinctly understood that the doors will be left open at least four hours after being loaded, as when hot flour is put into a cold car that has an all-metal roof or end exposed in the interior it causes the metal to sweat, and the moisture dropping down on the sacks injures the flour.

REPAIRING FOREIGN CARS

In handling repairs to foreign cars which are in need of heavy work, either on account of deterioration, damage or wreck, the following should be remembered:

It is necessary that division terminal stations which are equipped with planing mills, compressed air facilities and steel working tools, give attention to the classified repairs on foreign cars which are of such construction, so that when repaired and put in first-class shape they will be available to our service. Under these circumstances cars with steel underframe, steel center sill or steel draft arms (arms to extend at least 30-in. behind bolster) should be selected in the order named and box cars should be given preference over other types.

We should aim to do the best possible work on foreign cars

coming to our repair tracks and turn them out in fit condition to properly meet traffic and commodity requirements. For instance, when a foreign car comes in for attention to the draft sills or steel underframe, if in such condition as to require also new sheathing, roof, floor or lining, end or posts, doors, bolster, or draft gear, etc., and suitable material is in stock the car should be put in first-class shape. The main shops at Milwaukee, Dubuque, Minneapolis, Green Bay and Tacoma are doing this now. This plan must be strictly observed in order that we may be in a position to bill against foreign lines to an equal or greater amount than they are billing us for repairs to our cars on their lines.

It was mentioned in the paragraph just preceding that steel underframe equipment or cars of like construction should be selected, the reasons being obvious. On the other hand, cars more than fifteen years old, which are of weak construction, generally equipped with short wooden draft timbers, and which appear to be in an unsafe condition to run and if rebuilt would probably not stand up under present service conditions, are to be set aside, written up on form CD-27 for disposition and this office will in turn take the matter up with the car owners to secure authority to strengthen and rebuild, dismantle or send home empty. Every effort must be made to keep such cars off the railroad and where found empty in this condition they should be held so as not to cause damage and difficulty to other good cars in service, also where coming to repair tracks under load they should be transferred and reported as above, unless we have a near connection with the car owner.

Precautions should be taken not to spend more than \$250 on any foreign car of 40 tons capacity or over and which is less than 12 years old. Roughly speaking, this expense will permit the application of an entire new roof, two side doors and light repairs to the draft gear, couplers, boxes, wheels, etc. It is not intended to apply a whole new superstructure or underframe, without obtaining the appraised value of the car from the owner and determining whether we can settle for less expense than the authorized repairs.

Cars of 30 tons capacity and equipment more than 12 years and not over 18 years old should be limited to \$100, which will allow for the application of an entire roof, or two ends, or flooring and doors, or new sheathing, or two longitudinal sills, draft sills and end sill, but as already stated only such cars which are equipped with steel underframe, steel center sills or steel draft arms extending back of body bolsters should be extensively repaired. Cars not coming under the above classes should be held for disposition.

Cars must be written up promptly on form CD-27 and when the report is received in this office we will send a copy of form CD-27 to the owner. If a reply is not obtained from the car owner within 30 days, we will take the matter up with our executive officer who will get in touch with the car owner's executive for immediate response; the same is true of material required from owners to make repairs to their cars. It is not intended to hold cars more than 30 days and the foreman should keep after the master car builder continually if instructions for disposition are not received promptly. Billing must be kept up to date and properly checked at all times.

General Conditions Governing the Repainting of Foreign and System Freight Cars

The preservation of freight car equipment of all railroads will be maintained by the necessary repairing and restenciling. When paint on freight equipment has perished to the extent of permitting the steel to rust and deteriorate or the wood to become exposed to the weather, the car should be repainted. The body (including the roof) should be entirely repainted if for any reason it is found necessary to re-

paint one-third or more of the car. Before applying paint to steel or wood it should be scraped so as to clean off all blisters and loose paint, also removing protruding nails and tacks.

When repainting freight equipment cars, two coats will be applied to all new parts and old parts of the body which have been reworked causing removal of the paint. One coat will be applied to parts where the old paint is in good condition. Should the old paint be found in such condition as to require two coats, they may be applied.

The station marking showing where the car was last weighed should not be changed unless the car is reweighed. The stenciled letters and numbers on all freight equipment cars will be maintained and the identity kept bright. When the lettering or numbering is found in bad condition, the identifying marks should be renewed either by repainting the car or by applying new stenciled letters and numbers. In selecting cars for this purpose, preference should be given those on which the marking and painting is in the poorest condition. Do not cut stencils for special marking such as the monogram on Great Northern, Santa Fe or Southern Pacific cars.

If there is not sufficient paint on the car properly to retain the new stenciling and the condition of the car does not justify entire repainting, one coat should be applied as a panel back of the stenciling so that the paint used in applying the numbers and letters will hold, otherwise the marking applied will soon become illegible, making it necessary to again apply the identity marking within a short period. Detention of equipment from service for painting should be avoided, when possible. A great deal of this work can be done to open cars in transportation yards when under load in storage.

These instructions apply equally to foreign and system cars and all should be repainted in accordance with the above instructions when on repair tracks, regardless of ownership. Charges for repainting and restenciling are to be made in accordance with the A. R. A. rules.

Date and Year Built

The A. R. A. rules provide that after September 1, 1919, cars will not be accepted in interchange unless stenciled showing the month and year built, or bearing a badge plate giving this information. Cars built prior to 1895 may be stenciled "Built prior to 1895" or bear a badge giving this information. In the case of tank cars, the body and tank should bear distinctive dates unless constructed at the same time.

Repairing Cars at Loading Tracks

At many terminals there is a loading or transfer track where cars are lined up and are not switched for almost 24 hours. At places where these conditions exist every effort must be made to have the proper number of men assigned to inspect and to repair all possible defects on these cars. There is much work that could be done even to the extent of caring for the air brakes. Brakes that are out of date could be cleaned and after they are cleaned the aid of a switch engine could probably be gotten to assist in testing the work at its completion. At this time the piston travel could be checked and the hose tested for porosity. All work done on cars at these loading points relieves the outside yard of just so much work, and inasmuch as it is much safer working on a car where there is no switching, as stated before, the efforts of all should be concentrated on this feature.

Repair Parts and Tools

Inspectors must keep constantly on hand for repairs a supply of all parts of the equipment that are liable to get out of order and which can be replaced while the car is in the yard. However, unless the proper tools and appliances are at hand, nothing will be accomplished, therefore, inspec-

tors should see that they are furnished with the necessary tools. Air brake inspectors should have with them at all times a pipe wrench, for use on the train line and retainer pipe, an S-wrench of the proper size to tighten up the pipe clamps, a coupling groove cleaning tool, which should always be used when renewing gaskets, a cotter key and lever pin drift, and a supply of cotter keys and nuts of different sizes. There should be no excuse for failing to have the necessary repair parts and tools with which to apply them with, because inspectors and repair men would be of little use if they were not able to repair defects which they find.

Old Date Air

All cars marked for bad order triple valves or brake cylinders, as where the brakes either will not apply or leak off quickly, should be treated the same as cars with the brakes out of date (system cars 9 months, foreign cars 12 months). On repair tracks all cars with the aforementioned defects must be repaired but in yards a certain amount of discretion will have to be used. Cars loaded with manifest freight which cannot be held a sufficient length of time to make the necessary repairs, will have to be allowed to proceed, but the car must be properly carded and when its destination is a terminal, must be marked bad order when empty, stating the reason. Empty cars which are to be assigned to shippers to be loaded on our lines must positively have the brakes cared for before being allowed to proceed.

Damage and Loss

Damage or loss to any car, due to wreck, derailment, cornering, sideswiping, flood, overloading, explosion, collapsing structures, or unconcealed fire damage, including cars on ferries or floats; also damage due to storms where the car is derailed or destroyed is chargeable to the railroad holding the car in its possession at the time. Defect cards are not required for any damage so slight that no repairs are necessary, nor for raked or cornered sheathing, roofing, facia, or bent or cornered end sill, not requiring the shopping of the car, the receiving line to be the judge. In case of interior fire damage, in any class of car, if evidence of such internal damage was not discernible externally, it is considered an owner's defect. When flooring planks are out and can be seen from the outside of the car, they are cardable defects. When paint is missing in spots, due to hot lading, such as pig iron, billets, cinders and blooms being loaded in cars, is not a cardable defect unless the damage is such as to require the shopping of the car.

Temporary Transverse Tie Rods Applied to Cars with Sides Spread or Bulged

Owners are responsible for the expense of applying tie rods, when these are necessary to allow the equipment to pass the clearance limits of the handling line.

DEFECTS OF VARIOUS PARTS OF CARS

Sills

Sills of both wood, steel, and steel underframe cars and cars with metal draft arms, should be carefully inspected to see that they are not destroyed, cracked or split on account of draft bolts working in sills or being buckled or broken. Broken, cracked and buckled sills are generally found directly in front of or at the back of the body bolster.

Method of Splicing Sills of Wooden System Freight Cars

WOODEN CARS: Longitudinal sills may be spliced at both ends, except that not more than two adjacent sills may be spliced at the same end of the car. The splicing of any sills between cross tie timbers will not be allowed. The splice may be located either side of the body bolster, but the nearest point of any splice must not be within 12 in. of the

bolster, excepting center sills, which must be spliced between the body bolster and cross tie timber, but not within 24 in. of the body bolster.

The splicing of longitudinal sills other than center sills is to be done in accordance with Fig. 1; old splices now on cars may be repaired. Center sills must be spliced in accordance with Fig. 2, when new splices are used. This blueprint provides for a uniform splice for the various classes of cars and must be followed as far as practicable to obtain uniformity and interchangeability of splices. Old splices now on cars may be repaired.

Foreign and Private Line Cars: Longitudinal sills when broken may be spliced in accordance with the A. R. A. rules

Fig. 1. Splice for Longitudinal Sills other than Center Sills

of interchange and the details of the splice must conform thereto.

Note: In splicing the sills of foreign and private line refrigerator cars, care must be exercised to see that the insulation is replaced in accordance with the original construction to avoid being penalized for wrong repairs in the case of foreign equipment.

Center Plates

Body and truck center plates should be carefully inspected to see that they are not broken and properly secured in place, the bolts and nuts tight and the center pin in position properly secured to prevent loss when cars are turned over on dumping machines.

Truss Rods, Struts, Saddles, Washers and Nuts

On empty cars passing over repair tracks, through transportation yards or in storage, every opportunity should be taken to see that truss rods are properly tightened, so that

Arrangement of Draft Timbers and Wooden Center Sills

Draft timbers and sub-sills on empty cars on all repair tracks must be tightened up and other work done in accordance with standard car maintenance regulations, lock nuts to be applied to all bolts.

When applying new center sills, one keyway only must be cut in the sill, omitting the keyway nearest to the end sill. When applying new draft timbers, one keyway only must be cut in the timber; the keyway in the center sill corresponding to the keyway omitted in the draft timber should be filled with a piece of wood nailed in place. Draft timbers are to be framed and bear against the inside face of the end sill. The use of fillers between the bottom of the center sill and the top of the draft timber will not be allowed.

Cars with Low Center Line of Draft Gear

Every precaution must be taken in connection with cars having a low center line of draft, especially those cars not equipped with draft sills, in order to avoid the wheels interfering with the sills on curves, resulting in broken flanges. It often happens that cars which are difficult to inspect, on account of being low hung, do not receive the careful inspection of side bearings necessary, so that equipment proceeds with side bearings engaging each other, causing derailments.

Continuous Draft Gear

Cars are not acceptable in interchange when equipped with stem or spindle coupler attachments or American continuous draft rods.

Draft Gear

Inspection should be made to see that the draft gear and all its parts are in good condition, carrier irons and straps tight and in place. The coupler should be gaged to see that it is not worn beyond the limit permitted by the A. R. A. gage, also to see that it does not contain cracks that would result in failure. The coupler should be at the proper height as required by the federal Safety Appliance Law. Yoke rivets should be in place and tight. When new rivets are being applied at shops where the facilities are available,

Fig. 2. Splicing of Center Sills in Conformity with the Rules of Interchange

the cars will have at least 1 1/2-in. camber in the center. Turnbuckles should be properly secured from turning, truss rod saddles, struts and needle beams should be thoroughly held in place and should function properly at all times. Truss rods are to be tightened firmly in place and turnbuckles locked where possible; also saddles are to be properly located and the truss rod nuts on the end sill are to have full bearing and full thread hold.

Draft timbers. Draft timbers must not be spliced.

Draft Timber Bolts

Draft timber bolts 1 1/8 in. in diameter must be applied to all system cars having draft timbers, center sills or draft rigging applied, these to replace 7/8-in. diameter bolts removed from empty cars on all repair tracks.

they should be 1 1/4 in. diameter in accordance with the A. R. A. requirements.

The coupler operating mechanism should be in operative condition so as to properly operate the coupler, to avoid safety appliance defects.

It is considered good practice to lubricate couplers as they pass over repair tracks by applying rail grease or the thick sediment taken from the bottoms of oil tanks, which may be applied with a paddle or a piece of waste fastened to a stick. This lubrication is applied to the wearing face of the guard arm of the coupler, and to the knuckle only where the knuckle throwing device bears, to assist in the free operation of the coupler. Care should be taken to keep lubricant off the knuckle lock and the bearing surface of both knuckle and lock.

(To be continued.)

SCHEDULING AND ROUTING WORK IN THE A. E. F. SHOP

Methods Used to Increase Production in the Shop of the Railroad Engineers at Nevers, France

BY MAJOR C. E. LESTER

Formerly Gen. Supt., 19th Grand Div., Transportation Corps, A. E. F.

THE writer has long been an advocate of systematic routing of parts in locomotive repair shops and is at the present time more than convinced that routing and scheduling of parts is a practical necessity in a shop on a day-work basis that is of such a size that the machine shop foreman particularly and all other department foremen in general do not know from actual contact the exact status of individual pieces of work.

In shops where no routing system is in effect some pieces of work invariably get buried or lost from sight until the part is actually needed, with the result that the foreman must pay penalty overtime to get the work ready or delay the locomotive for which it is needed. In any case, no system means lack of system and co-operation, with inevitable delay due to haphazard methods.

The routing and scheduling system and the machine-shop percentage board, presented herewith, were inaugurated under

and depleted of workmen it was the only shop in France where the 1,160 Pershing engines and the 476 Belgian U. S. A. engines could get anything except running repairs. It was also required to handle heavy repairs for the Est., Paris-Orleans, Nord and Paris, Lyons & Mediterranean railways as well as all types and sizes of narrow-gage locomotives (French, Belgian and German), road rollers, tractors, pile drivers, locomotive cranes and the assembly of forestry locomotives.

It is an undisputed fact that method and system are the greatest producers. After about four weeks of operation without what could be called a definite plan of operation, this system was put on trial. Its results were at once apparent and almost immediately justified its adoption in many ways, one in particular being that the general foreman had his finger on the pulse of the organization at all times and, like a general with his war maps and service of information, could plan his strategic moves to the confusion of his old enemy—haphazard methods.

It is a well-understood fact that (a) methods of application and (b) sympathy or the lack of it are the prime movers in establishing any system. This system met with a hearty and enthusiastic reception, which insured its success from its inception.

The method (so called) prior to the adoption of the scheduling and routing system was the custom of establishing a

Fig. 1. Percentage Board for Recording Progress of Work

the writer's direction in the Nevers, France, locomotive shop to expedite repairs. Incidentally, no claim is made for originating this method. The system was not new, but rather an application of principles of routing used here in the states in various shops, and was worked out "over there" by men in the shop who had come in contact with such systems in the U. S. A.

The shop was new, the organization was in an embryonic stage, our soldier mechanics were men of unknown ability and experience, our gang leaders were trial selections, the department foremen (commissioned officers) were an unknown quantity, there were no opportunities to go out and select, no time to waste on lengthy educational methods, we had what we had and got nothing else.

The necessity for a smooth-running shop and the maximum output possible was a fact so apparent that there was no disguising the necessity of devising ways and means of crowding the work to the extreme limit. The shop was the only all-American locomotive repair shop in France, completely officered and manned by soldier mechanics of the American army, and as the French shops were run down

completion date for each locomotive undergoing repairs. This practice is the usual one where the erecting shop foreman looks over the inspection report for the locomotive concerned and "reckons as how" he can get the engine out in an estimated number of days. He has no reliable detailed data on the status of work in the various departments, no particular method of calculation; he bases the date on his experience of the time it should take to complete the repairs, but, like the weather prophets, he occasionally makes a good guess.

There are evidently three factors that must be carefully considered and conscientiously performed to make the scheduling and routing system function properly. First, the joint inspection by boiler and machinery inspectors should be a most thorough and competent one, as it is on this that the "schedule engineer" bases his figures, and a poor inspection will upset all calculations and incidentally the whole shop schedule.

Second, the constants used for individual locomotives and their various parts must be obtained by thorough, careful consideration of all conditions that affect the progress of parts through the shop. A constant sheet worked up for one

shop would be valueless in another unless conditions were very similar.

Third, the schedule engineer or routing clerk, as he is variously called, must be thoroughly familiar with shop conditions and facilities; he must have sufficient mechanical ability to carefully judge the progress of work in order to successfully check the work; he must at all times keep in mind the fact that any newly established system ceases to be an innovation after a short time and that as it ages it should become freer running and can be speeded up, and should be in position to shorten up time here and there in order to force production; the summary of these qualifications is that he must be a worker and a schemer.

In connection with the operation of the system a photograph of the locomotive shop chart of February 1, 1919, is shown, with the output of classified repairs for the months of December, 1918, and January, 1919, shown on the right

percentage board, located in the machine shop foreman's office, shown in Fig. 1, and a record kept by each gang leader, Fig. 2.

The sketch of the percentage board explains itself insofar as the general design of the board is concerned. It is only necessary to add an explanation of the method employed in working the board. In the column headed "Order out" are listed all locomotives undergoing repairs in the erecting shop in the order in which they are due out. This is used to determine at a glance whether the work in the machine shop is progressing properly, so as not to delay the assembling of any certain locomotive in the erecting shop. The next two columns are self-explanatory. A column for shop order numbers is necessary at these shops, as a shop order is issued for each locomotive repaired and all labor and material charged to the shop order number instead of to the locomotive number. In the column headed "Date Out" is placed the date the locomotives are due out of the erecting shop.

The remainder of the board, it will be noted, is divided into columns for the various locomotive parts, each having three sub-columns, namely, condition, progress and remarks. In the first column is placed the condition of the part when received in the machine shop. In the column headed "Progress" are shown figures to denote what per cent the work has progressed. When work is started on any part the figure 25 is placed on the first line of this column, indicating

Chart of Classified Repairs, Nevers Shop, Feb. 1, 1919

A Scene in the Erecting Shop

of the board, a total of 45 and 50, respectively, an increase from 14 in August and 21 in September.

The service record board was used to show all locomotives on hand in the shop yard each day until the locomotive left the premises. It will be noted that but 28 locomotives were booked for February. This is explained by the fact that 500 men were ordered back to the states on February 1, 1919.

Material Checking System

On account of the great number of locomotive parts necessarily handled in the machine shop and the possibility of some of these parts being allowed to remain at any one machine a longer time than necessary, thus delaying the completion of the locomotive in the erecting shop, a material checking system was instituted so as to be in position at all times to tell without difficulty the exact status of all work in this shop. The appurtenances of this system consist of a

that the work has progressed 25 per cent. Parts sent to the machines or parts received back from the babbitting shop or other shops, where they have been forwarded for repairs, are considered as 50 per cent complete, and that figure is placed on the second line. Parts sent from machines to the bench gangs are considered as 75 per cent complete, and that figure is entered on the third line. When the parts are completed 100 per cent is placed on the fourth line. Lesser divisions of progress could easily be used, but it was found that four 25 per cent divisions were small enough for our purpose.

The question that will naturally arise after the above explanation is from what source the information is received as to the progress, so that the entry can be made on the percentage board. This information came from the records kept by the various gang leaders, on the form shown in Fig. 2. Each gang leader had one of these forms on which he entered the progress of the work of his gang and which he turned in at the close of each working day. From this form the clerk in the machine shop foreman's office entered the information on the percentage board.

The column headed "Remarks" was used in cases where locomotives had been scheduled and the parts had not been received in the machine shop, etc. In such cases the word "None" was entered in this column. In cases where parts were received in the machine shop and work on them had not

been started the word "Over" was placed in this column. When parts were sent to other shops to receive repairs and were later to be returned to the machine shop for completion, the shop to which the parts were forwarded was written in this column.

The percentage board enabled the machine shop foreman to readily ascertain the progress of all work in his shop, and if the work was not progressing as it should so as to enable the erecting shop to complete the locomotive by the scheduled

a locomotive inspector, who after the completion of their inspection made a joint report to the general foreman showing the principal repairs required. This joint inspection report when received by the general foreman was passed on to the route clerk, who was located in the general foreman's office, with necessary instructions as to the date and location for the engine. From this joint report the route clerk determined the class of repairs that were to be made and the number of days it should take to complete such repairs. The

date, he could take such steps as would be necessary to bring about the completion of the work in the proper time. This system has proved of great assistance in the supervision of the machine shop.

Locomotive Scheduling and Material Routing System

Frequent delays were experienced, causing necessity for a change in the established date for the completion of locomotives, through the failure of one or more of the shops to finish their work on parts prior to the time they were needed by the erecting shop for application to the locomotives.

In order to overcome this hindrance in the progress of completing locomotives, the "routing" and "scheduling" system was placed in operation during the month of August, 1918. By "routing" is meant the determining of a route or path over which the parts must necessarily pass in the course

schedule of classification and the number of days allowed for each class of repairs in effect at the shops were as follows:

Class	Nature of Work	Number of Days
One.....	New engine (rebuilt).....	Twenty-eight or more.
Two.....	New firebox and general repairs.....	Twenty to thirty.
Three.....	Light repairs to firebox, flues changed and heavy repairs to machinery.....	Ten to twenty-four.
Four.....	Tires changed or turned, driving boxes renewed, and other necessary repairs to machinery.....	Six to eighteen.
Five.....	Running repairs (heavy).....	Two to ten.
Six.....	Accident repairs.....	Depending entirely on extent of damage.

For each class of repairs there was a more or less definitely established "Mastersheet." For the type of master sheet used reference is made to Fig. 3, compiled for a Consolidation type locomotive requiring class Three repairs and scheduled to be completed within 24 days. It will be noted that each shop has its column wherein are listed the various parts

SCHEDULE FOR 24 DAY LOCOMOTIVE

Erecting shop	Machine shop	Boiler shop	Wheel shop

Fig. 3. Schedule for a Locomotive to be Completed In 24 Days

of repairs. By "scheduling" is meant the establishing of a date when each part is to be received in a certain shop and a date for that shop to complete its work on the parts and pass it on to the next shop. This "routing and scheduling" system was handled entirely by a route clerk and one assistant. It may be well to add that these men were mechanics of known ability to competently judge the status of the work, time required, etc.

Immediately upon receipt of locomotives at the shops for repairs a joint inspection was made by a boiler inspector and

of the locomotive handled by that shop. The figure appearing opposite each item is the scheduled number of days for the completion of each operation. For example; the figure two opposite "Engine Stripped" in the erecting shop column, indicated that the erecting shop is to have the locomotive stripped and material delivered two days after the engine arrives in that shop.

The class of repairs, and number of days in which to complete the repairs having been determined, the next step is to inform the various shop foremen when the various operations

in their respective shops are to be completed. This is accomplished by the use of a repair card, shown in Fig. 4. This repair card is compiled by the route clerk and distributed to the various shop foremen concerned. Using the master

tank shop, Fig. 7 for the wheel shop and Fig. 8 for the pipe and welding shop. These repair cards enable each shop foreman to know at all times just what work he has ahead of him and by what date the various items must be com-

Fig. 12. Machine Shop Material Check List

This despatch board enables the general foreman to tell at a glance just what locomotive parts are due for completion on any certain day, and indicates to him and others concerned, just what parts are delaying the completion of the locomotive in the erecting shop.

Each morning the route clerk refers to the despatch board and determines therefrom what operations should have been completed at the close of the previous working day and enters on a check list the locomotive numbers opposite each item that should have been completed. The check lists used for the erecting shop, machine shop, for all other shops, are

shown in Figs. 11, 12 and 14 respectively. The route clerk then visits the various shops determining whether or not the operations have been completed. If completed a line is drawn through the locomotive number. If not completed, an explanation and the prospective date of completion, are secured from the foreman in charge of the shop wherein the delay has occurred and this information is entered on the check

TRACK STOPS FOR ROUNDHOUSES

BY NORMAN MAC LEOD

It frequently happens, due to carelessness or poor judgment on the part of railroad employees, that locomotives are run too far in a roundhouse or other points in railroad shops or yards, resulting in the locomotive being derailed or in

.....

Fig. 16. Form for Reporting Delayed Material

tages over the former system, and brought about very beneficial results, the most important result obtained being that for which the system was originated, namely, the elimination of holding locomotives in the shops past their scheduled date.

The stop shown in Fig. 1 is made in right and left hand

Fig. 1. One Piece Track Stop for Application at the End of the Rail

patterns, and is intended for use at the end of a track. It is provided with an extended concave portion to receive the wheel and stop the locomotive should it be run too far. The other type of stop, as shown in Fig. 2, is made in two parts,

Fig. 2. Two-Piece Track Stop for Application at Any Point on the Rail

which are bolted to and project above the rail head. It can be applied to the rails at any point that may be desired, even at the joint between two rails.

The use of such stops will prevent many expensive and dangerous accidents, and track stops made to these designs or other similar devices should be used wherever such trouble has been experienced.

FOOLS RUSH IN WHERE ANGELS FEAR TO TREAD

The General Manager Gets Some Inside Dope on Causes of the High Cost of Locomotive Repairs

BY HUGH K. CHRISTIE

GIBBONS, the general foreman read and re-read the announcement. Reflectively he laid down the railroad magazine and stared vacantly at the red-lettered cover. His clerk eyed him curiously.

"Any local news along the line this month?" he finally asked as he pushed over Gibbons' mail.

"Nothing at Grand Falls," responded the boss, "but an article here has got me thinking. The general manager says he'll give a fifty dollar prize to any railroad employee who will send him direct the best write-up on savings in any department on the road."

"Why don't you give him some dope?" said Leary, the clerk. "You and me have been watching leaks every day around here for some years and now's your chance. Fifty dollars is fifty dollars you know."

Gibbons shook his head. "Don't pay, Leary," he replied. "If we knew as much about saving as the big fellows did why—why, we'd be on their jobs. You know how I get bawled when I start suggesting. I would like to tell them a few things, though," he added absently.

"And the fifty dollars, too," reminded Gibbons' understudy.

"Ain't the money," said the boss, "but I would like to poke up a hornets' nest around here and get some material. Say, save that magazine for my noon hour," he abruptly commanded—"I'm going to the store," and the foreman pulled on his hat and started through the shop toward the little office at the end of the long brick store building.

Gibbons gave no heed to what was taking place about him, as he swung down the pit-side. The general manager's announcement kept pounding in his brain. He did not care to tell Leary that the fifty dollars meant more to him than the voicing of his protest against inefficient performance. He wanted those fifty iron men and wanted them badly. Wasn't he going to the community dance in a week and wouldn't he have to be all dolled up? Fifty dollars would do the trick nicely without cutting a hole into his two weeks' check. The idea was how to go about it, for William Gibbons was no hand to produce exploded verbal kicks in polished written form for a G. M. to read.

He swung open the door to find the storekeeper in conference with a visitor, who was recognized at once by the sharp-eyed boss. It was Case, the general storekeeper.

"How are you, Mr. Gibbons," he said as he reached for Bill's hand. The enthusiasm, however, was all on his side. With a gruff, "howdy" the foreman turned his attention to the storekeeper.

"Say," he announced, "we're all out of D. S. 5 springs for Engine 397. She was due out tomorrow—I've got her wheeled and blocked waiting for 'em."

The storekeeper looked wearily at Gibbons and then turned toward his own boss for some suggestion.

"Hear about this before?" asked the general storekeeper. "Yes," replied the local man. "I wired to Sagum Hill but didn't get an answer."

The general storekeeper looked toward the frowning foreman. "Why—why don't you get some out of the scrap."

"I knew it!" exploded Gibbons. "All I hear around here is, 'Look in the scrap!' Good Lord! what you fellows doing these days? Running the store department on scrap! Say, I got a limited pay roll on labor and I ain't got no time to waste hunting scrap."

The general storekeeper laughed easily.

"Don't get excited, Mr. Gibbons," he remarked. "We have got our limits to work inside, ourselves. The proportion must be maintained, you know."

"Proportion! What proportion?" growled the shop foreman.

"The proportion between material and labor in railroad-ing," smoothly responded the general storekeeper as he relit his half consumed cigar and regarded Bill, the foreman, complacently.

"You see it's just like this," he continued, noting Gibbons' blank look. "Material should run about 40 per cent and labor 60 per cent on your cost of back shop repairs. At the present time we are maintaining our figures, but the mechanical department has gone way beyond theirs. From this it is evident that the store department is more efficient than

"We're All Out of D. S. 5 Springs for Engine 397."

your department, and that is why I suggested that you look the scrap pile over for waste of material."

The local storekeeper expected one of Bill's daily brain storms over shortage of material but none was forthcoming. In silence Gibbons rubbed his chin and stared reflectively at the visitor.

"Those the customary figures?" he finally questioned.

"They certainly are," responded Case. "Any complaint against them?" he added.

"Don't know," remarked the shop boss thoughtfully. "I do know one thing, however, and that's this: The store department always makes a hit when it cuts down material no

*Entered in the Railway Mechanical Engineer prize story contest.

difference how it affects the mechanical department, which can't squeal because it has always been considered the non-revenue end of the pike. My boss is trying to save money by getting more material and your boss, the purchasing agent, is cutting requisitions. If it comes to a show down the store wins out.

"You store fellows are always talking about saving and reclaiming scrap," continued Bill, "but I say, why don't you get decent material that won't have to be scrapped. We order one thing and get something else."

The general storekeeper blew out a puff of smoke and grinned.

"Better tell the general manager about these things, Mr. Gibbons, and see who is right," he finally remarked.

For a solid minute the shop boss stood staring vaguely beyond the speaker. Evidently the general storekeeper had not seen the announcement in the magazine. Suddenly Gibbons started for the door. As he started to close it he turned first to the storekeeper. "Chase those springs, Bill?" he requested. Then a sharp glance toward Case. "Thanks for your advice you gave me a second ago—believe I will give the G. M. a few tips." Without another word he disappeared.

Gibbons went through the rest of the working day automatically. No one noticed that he acted peculiarly different, but his clerk appeared surprised when Gibbons asked him to get the cost sheets for overhauling back shop locomotives by months for the past year. Leary was further puzzled to see his boss carefully roll up the data and take it home that night with a mass of notes which the under foreman had submitted.

Throughout the evening meal the boss was unusually quiet. It worried his wife.

"Anything wrong at the shop today, Bill?" she anxiously asked.

"Nothing out of the usual, Peggy," came the response. "But I'll be busy on some work tonight and I'm just checking it off in my brain."

"Is it for the shop?" she questioned.

A grim smile came over her man's face. "Maybe, and maybe not—maybe I'm digging my own grave, but what I'm figuring on doing is writing the general manager for a suit of clothes. I'll either get them or get something else that I ain't looking for."

Bill would not satisfy his wife by answering any other question, and as soon as the dishes were cleared from the table he produced his railroad papers. Patiently he worked over locomotive costs of heavies and lights. He had repairs running from five hundred to four thousand dollars. Carefully he separated the labor and material costs grunting astonishment at his results. He whispered an oath at the final averages.

In repairing power *90 per cent represented labor and only 10 material*. On a \$2,000 repair job only \$200 was used for material. Gibbons discovered that on a basis of 40 per cent for material and 60 per cent for labor \$500 should be the proper labor charge. Instead, it was \$1,800. It was \$1,300 too much.

Then he began going over the work sheets. He picked out scores of places where new material should have been used but on account of none being in stock, other engines were robbed or expensive reclaiming was followed.

At one time a consolidation engine required a left steam pipe. An engine waiting shop had been robbed for a pipe although its front end required but minor repairs. The front end and netting were removed. The petticoat pipe was disconnected and the steam pipe joints broken for the sake of this pipe needed for the engine going out. It required over \$100 worth of labor to apply the new pipe which would not have been removed if material had been in stock.

Gibbons groaned as he remembered disconnecting cross-heads and pulling down guides for back cylinder heads from good engines, in order to rush back shop repairs. In the majority of cases, the store shortage had cost him hundreds of dollars.

He had made forgings that cost many days work for the lack of castings. He got together the figures representing wasted labor looking over the scrap pile. He then added the cost of reclaiming. Gradually his data disclosed the fact that the engine which cost approximately \$2,000 for repairs could have been repaired for \$1,000 if \$400 had been used for material instead of \$200. To get the other \$200 worth of material he had spent over a thousand dollars in labor.

It seemed incredible. Gibbons knew that this was a heavy

They Had to Rob an Engine to Get a Left Steam Pipe

repair but his light repairs brought out the same approximate proportion.

All excitement the general foreman started his letter to the general manager. It was a long hand affair with a mass of figures taken from the official report. In it were typical illustrations—in other words, actual evidence. At the end of the article the foreman wrote as follows:

"Mr. Corey, if you went to a shoe store and asked for a pair of shoes, what would you think if the clerk said: 'We are entirely out of shoes, but we have some nice leather boots. They cost twice as much but they are your size. You can cut the tops off and throw the unused parts away. Otherwise, I guess you must go without unless I wire for some and I know you can't wait!' Now this is the fix the mechanical department is in, Mr. Corey. We must butcher up good stock or do without. Years ago material was cheaper than labor, but today the reverse holds true. I do not believe in waste, but unless you get your store figures up to 40 per cent of your figures of repair there is going to be a big waste in spite of the best care along lines of supervision."

The foreman signed his letter with a sprawling William Gibbons and then added his title. He then re-read the article in the magazine. It said to send the article direct to the general manager. Gibbons inserted the letter in a railroad envelope. He pulled on his shoes and started for the drug store for a stamp. The boss did not intend to have his information side tracked by going through the railroad mail.

"Ten and ninety, eh, instead of forty and sixty? Somebody's going to get their eyes opened. If they open right I get my suit of clothes—and if they open wrong I guess I'll have to look for another job." With these words on his lips William Gibbons went to sleep.

Gibbons slept late the next morning and his better half did not have time to question him. By evening she had forgotten the whole affair. Not so with Bill. All day long vague misgivings seized him. Had he done right in pursuing this course? Collings, the purchasing agent, stood very close to the general manager. It had often been said that the man who forced an issue with Collings was bound to get it, using a shop phrase, "in the neck." The day went by without a hitch, however, and the shop superintendent and master mechanic seemed unusually cheerful.

Next day trouble appeared on the horizon—about noon to be exact. The shop efficiency man had got back from headquarters on the ten o'clock train and went into the master mechanic's office immediately. Then the shop superintendent was called and finally Shop Foreman Gibbons.

It was a chilly atmosphere that the shop boss struck in the master mechanic's office. He was asked to be seated and the inquisition was on.

"William," began the master mechanic. "Gordon has just come from the superintendent of motive power, and he tells us strange things. The big boss told him that the general manager, had called him up asking about a shop foreman by the name of Gibbons, who had given him some dope on savings. Wanted to know what kind of a fellow you were. Now the big boss held back on recommending you very highly until he knew what you had written, and, although all of us here have thought pretty well of you, we no doubt have been mistaken in you if you are making a practice of taking things over our head." The master mechanic gazed sternly at the shop boss as he spoke.

The efficiency man grinned at Bill's abashed face. There was no love lost between them.

"Spit her out, Bill," broke in the shop superintendent.

The general foreman hesitated a moment and then began.

"Yes, I wrote him all right and told him one of the best ways of saving money around this plant."

"Why did you do that?" asked the efficiency man.

"Because he asked me to," returned Gibbons.

"Asked you to!" exclaimed the master mechanic.

Bill slowly reached in his back pocket and produced the railroad's magazine.

"Read it," he said. It was passed from man to man. None of them had noticed the article before.

"I ain't carrying anything over anyone's head," began Bill stoutly. "This was no regular railroad business."

"But you should have at least let us see it," returned the master mechanic. "Why didn't you let us read it first?"

When Gibbons was cornered he welcomed a fight. "Well, I'll tell you," he flared up, "why I didn't. Before anything like that would pass this here board of censorship there wouldn't be much left."

The efficiency man glared at the foreman's remark but the eyes of the master mechanic looked cold as ice.

"You would certainly condescend to show us a copy of the letter for the sake of the men you work for, wouldn't you?" he asked sarcastically.

Gibbons shook his head in the negative.

"It can't be done 'cause I wrote it longhand and never saved a copy."

"Then kindly tell us what you said," demanded the master mechanic.

Gibbons gave a detailed account of the letter. The jaws of his listeners dropped at the freedom of expression.

"Did you tell him all that?" gasped the shop superintendent.

"Yes, and maybe some more," returned the general foreman. "It's the truth, ain't it?"

For several moments the master mechanic sat and stared at Bill. Could this be his easy-going foreman?

"Gibbons," he finally announced, "you have got more gall than a young hogger. You should have realized that the general manager published this article to excite an interest and a spirit of co-operation; and here you unload a stick of dynamite. Of course, I can see why you sent your article in direct, but you have given us but very little protection, and if the worst comes why we simply can't save you."

"Collings, the purchasing agent, has been a thorn in our flesh and also the boss's for a long time, but he stands so close to the general manager that no one has dared to produce the facts. Now re-write the thing out to the best of your memory and shoot it up here for typing, and hurry."

Obediently Gibbons arose and left the room. In silence the three remaining men stared at each other. "I'm afraid he's in bad," absently remarked the master mechanic, "even if he did tell the truth but—but Lord what gall!" he added.

The general foreman's second letter was turned in—a copy was hurried to the superintendent of motive power. The rest of the day went badly for the poor fellow. Every thing seemed to go wrong. He received vacant stares from his bosses. "Just about as welcome as a head full of bugs," he mournfully remarked to himself.

His wife sensed his depression as soon as he arrived home that night. He confided his troubles and finished by saying:

"I'm in bad, Peggy—the gamble wasn't worth it—I played

"I'm In Bad, Peggy."

for a suit of clothes and will probably get the bounce." All night long he dreamed of a fifty dollar bill chasing a suit of clothes, both being run down by Collings, the purchasing agent.

The morning of the next day was a repetition of the previous day's misery. That is, it was until the master mechanic got his mail. Another call came for Gibbons to report to the office. Indifferently the general foreman responded. He was callous to additional trouble. He entered the doorway. It was the same room and the same faces but the atmosphere was different. Had Gibbons been more alert he would have caught the difference.

Again he was asked to be seated. The master mechanic

was holding an opened letter in his hand with a green slip attached to it.

"Gibbons," announced the master mechanic in a stern voice but with a hidden twinkle in his eye, "I just got a copy of a letter from the general manager to the superintendent of motive power. He says some awfully nice things about you which you can read later on. Says he had been misinformed in the past and that from now on more attention would be paid to getting material, and material which the mechanical department specifies will come as specified. Speaks about details taken up later along this line and mentions that he intended writing you a letter of thanks later on."

The master mechanic was now smiling broadly. "Here is a letter from the superintendent himself. He wants to know if you can be trusted with the job of mechanical inspector. Tells me that that fellow Gibbons must have some kick in him when he dares to tell the truth."

The master mechanic's eyes fell again on the original letter. "Oh, yes, by the way, my copy from the general manager has your check for \$50. You see, you got the prize. Your nerve ought to get you to the top of the ladder, my boy, and I admire your spirit, but I wouldn't get in the habit of going much higher than your next officer in passing information, because it don't pay."

The efficiency man slipped out. Bill received congratulations from the shop superintendent, and thanked the master mechanic for his words of advice.

"Honest, Mr. Good," he confessed to the master mechanic, "it wasn't nerve—I didn't know any better, and, to tell you the truth, I wanted that money for a suit of clothes."

The superintendent and his boss laughed heartily. "Better dig out early tonight, Bill, and pick 'em out," advised the superintendent. "You've done enough good around here to last for years." These were the parting words Gibbons caught as he left the office with an unconfined joy in his heart.

The two men remained sitting at the desk and watched the happy Bill swing toward the back shop doors down the lane of busy machines.

"How did he get by? Can you beat it?" remarked the superintendent of shops to his superior officer.

"Well, I first thought that it was because fools will walk where angels fear to tread, but I guess I'm wrong, because Gibbons has proved he's no fool, and I know tarnated well you and I aren't angels. Let's just say it was taking advantage of a literal interpretation and let it go at that. He's paved the way for getting us material. Got any one picked for his job after he gets his new position?"

LOCOMOTIVE REPAIRS AT SHOP AND ENGINEHOUSE*

Thoroughness in Back Shop and Attention to Slight Defects at Terminals Needed to Save Fuel

BY LESLIE R. PYLE

Supervisor Fuel Conservation, Central Western Region, Chicago

LOCOMOTIVE maintenance is one of the vital features of railroad operation. During the past two years, locomotives all over the United States have been turned so rapidly through terminals that a great many times needed repairs have been dispensed with. So far as one can see, there is no indication of a decrease in business; therefore, now is the time to take a definite stand for a better standard of locomotive maintenance.

The writer would urge for consideration and adoption, the standardization of the best practices for each piece of work to be done. Aimless effort however diligent will not produce the results that are possible through a well-defined plan and a standard by which to gage every effort. These standards should be blue printed, each print containing written instructions describing in detail how each job should be handled. This will insure every shop or drop-pit doing the work in the same manner. When a better practice is developed, the print should be changed to cover the improvement. If this is conscientiously followed, every shop will be doing the work in what is known to be the best way. Improved methods and practical short cuts are always acceptable and suggestions offered by anyone in any position should have thoughtful consideration. We should encourage men in subordinate capacities to give us their ideas and such ideas, when found to be practicable, should be adopted and the employee given the credit for the improvement.

Although it is realized that enginemen can and do waste fuel with locomotives in first class condition, it is obvious that the engineer will have no control over the fuel waste due to cylinders out of round, valve gear out of square, etc. When we consider that from 85 to 90 per cent of the

total railroad fuel is consumed on the locomotive, there can be no doubt about the need for careful, painstaking preparation of the locomotive, first in the shop and then in the enginehouse.

Shop Maintenance

Naturally the shop is where the foundation is laid for preparation of the locomotive which will result in fuel conservation. Usually, when the locomotive enters the shop, it is accompanied by a work report showing what work is considered to be necessary. Too often when a locomotive is received in the shop, a council is held to determine just how little work can be done. This often results in work being neglected which should have been done in the shop, where the facilities tend to reduce the cost of every operation.

At present, but four to six per cent of the total heat developed is applied to the draw-bar in the form of useful work. Anything which tends to lower the efficiency of the locomotive is taken from the four to six per cent at the draw-bar and not from the 96 per cent total heat liberated in the firebox. This is why we lay such stress on the locomotive being thoroughly overhauled in the shop.

Bearing in mind that the power developed by the locomotive is produced in the firebox through the liberation of heat generated by the fuel when it is burned, we should consider the condition of the firebox and boiler when the locomotive is sent from the shop.

The firebox should be free from all steam leaks. Flues should be well set in the sheet so that there will be no trouble from flues leaking while the engine is in service. This also applies to welded flues.

Boiler sheets and tubes should be absolutely clean and free from scale. There should be enough well located wash-out plugs to enable boiler washers to keep the sheets

*Abstract of a paper read before the Western Railway Club, January 19, 1920.

and tubes clean through the use of properly designed wash-out nozzles.

Grates and grate bars should be in good repair with well-designed shaker levers which will make the shaking of grates under service conditions a practical operation. A locking device should be provided to hold the grates level under the fuel bed, thus preventing holes in the fire and burnt-off grate fingers.

Arch tubes should be applied to locomotives not already equipped. It should be known that the ends of the tubes are beaded or belled sufficiently to provide against any possibility of the tube pulling through the sheet. These tubes should be thoroughly cleaned if dirty when reaching the shop.

The front end draft appliances should be installed according to a definite standard which has been arrived at as the result of road tests. These tests should have developed the practical setting for the petticoat pipe if one is used, the draft plate and the size of the nozzle tip, to insure a free steaming locomotive burning the average quality of fuel used. Blue prints should be furnished all shops and roundhouses, showing the standard front end setting and size of nozzle tip for each class of locomotive. Front end appliances should be set according to this print when engines are turned out of the shop.

The petticoat pipe should be well supported on hangers which hold it in a direct line with the smoke stack to insure the exhaust jet passing through the center of the stack. The joints between the base of the nozzle stand and cylinder saddle, and between the nozzle tip and the top of the stand, should be perfectly tight. Steam leaks at these joints materially affect the steaming qualities of a locomotive.

Steam pipe joints should be thoroughly ground in, insuring no leaks here.

The superheater should be applied according to blueprints furnished either by the superheater company or by the railroad company. If these prints are followed, no other directions should be necessary.

It is important that the joints of the superheater elements be thoroughly ground in. Heat treated bolts of high tensile strength and elastic limit should be used to bring the joints to a seat and hold them there. Suitable bands and bridges should be used to keep the elements from moving in the flues and to hold them up, making it possible to blow soot and cinders from beneath the elements. The damper should be applied in such a way that the correct opening will be obtainable and be securely fastened to the damper shaft to insure its positive operation.

If the stack or cylinders are changed while the locomotive is in the shop, the whole machine should be leveled up and the center of the nozzle tip plumbed with the center of the stack to insure the exhaust jet passing through the center of the stack. This should be emphasized because it is a common thing to find the exhaust jet out of line with the center of the stack.

Before the locomotive leaves the shop, a hydrostatic test should be applied, making a final inspection of all joints in the smoke box, a cap being placed over the nozzle tip when making the test. This may appear to be useless work, but it has been a common occurrence to find engines just out of the shop with steam leaks in the front end.

With draft appliances well arranged to provide draft through the boiler and the firebox, it becomes necessary to go below the mud ring to insure an adequate opening in the ash pan which will admit sufficient air to burn the maximum amount of fuel consumed under any working conditions. This should be an opening which will not clog up with cinders or with snow and ice in cold weather. An opening which is covered with netting is not satisfactory as it is too easily stopped up. There are a great many loco-

motives in service today lacking sufficient area of opening through the pan to admit air enough for complete combustion under normal conditions. Knowing this, we earnestly recommend that all locomotives be provided with the necessary amount of opening through the pan. This may involve radical changes in pan construction but the results obtained from such changes justify the expense.

Steam is used primarily to haul the train. Circular No. 19 sent out by the Fuel Conservation Section, illustrates in a striking way, the loss of fuel due to defective steam distribution. This circular brings out the fact that from 9.4 to 18.4 per cent of the steam was wasted due to distorted valve gear.

While the engine is in the shop, all pins and bushings in the valve gear should be renewed if they are worn at all. This brings to mind a statement of a roundhouse foreman in reply to a question asking why he was allowing a switch engine to remain at work when it was noticeably lame. He replied that the valves were only a little bit out. There is no little thing when considering the setting of valves and the elimination of lost motion through worn pins and bushings.

There should be a definite standard of valve setting for each class of locomotive. Valves should be set according to this standard before leaving the shop. If this is done carefully and all lost motion removed from the valve gear through the elimination of worn parts, we have made a good start towards the economical use of steam.

In the shop, if the wear in the cylinders is 1/16 in. or greater, they should be re-bored. Packing rings should be supplied which have been turned to compensate for the material taken out of the cylinders. If the valve bushing is worn 1/32 in. near the bridges, it should be re-bored and the necessary rings supplied.

A good plan to insure packing rings of the proper size is to have a definite standard of boring practice, a specified amount being taken out of the bushing each time it is bored and the cylinder packing rings turned and marked to correspond with the mark on the bored bushing. If this plan is followed, packing rings can be kept in stock to compensate for the bored bushing.

After taking care of the valves and cylinders, we should give the engineer every assistance in using the right cut-off while running the engine by putting the reverse lever and reach-rod up in such a manner that they can easily be handled. We can all recall locomotives which have been sent out of the shop with the reverse lever and reach-rod in such a condition that it required both the engineer and the fireman to handle the lever. This does not lead to co-operation from the man who has to operate the locomotive.

The power reverse gear should be overhauled at the same time the engine is. Reverse gears of this type should be as good as new when leaving the shop. There has been a great fuel waste through power reverse gears creeping and it has been found due to leaks in the operating mechanism, worn parts, allowing lost motion to develop, or through poor or worn packing.

Air compressors should be in good repair when placed upon the locomotive in the shop. All piping connected with brake equipment on the locomotive should be put up in such a manner that there are no air leaks. It has been found by tests that leakage as high as 15 lbs. per minute existed on the engine alone.

Steam used by auxiliary equipment amounts to six per cent of the total heat developed. This is why we stress the maintenance of such equipment as mechanical firedoors, bell ringers, headlight dynamos, steam grate shakers, cylinder cock operators, etc. All auxiliary equipment should be overhauled and tested in the shop to insure the maximum of good service from all devices. Headlight dynamos should

be well taken care of and all valves to the dynamo in good repair, making it practicable to close them to prevent leakage of steam.

Devices or valves which have to be operated by engineers and firemen should be, wherever possible, within easy reach of them to insure the efficient operation of the device. When men have to go out of their way to reach valves, the full value of the device is not always obtained.

Hot boxes waste more fuel than people generally realize. If a locomotive is delayed 30 minutes with a hot bearing on a busy piece of track, this delay is not confined to the one train and engine, but is passed on to numerous trains behind, the loss being cumulative. Special attention should be paid to the fitting of brasses and weight distribution on the axles to prevent hot boxes on locomotives.

Radiation losses on a locomotive amount to approximately five per cent of the total fuel consumed. A large portion of this loss may be prevented by thorough insulation. It is recommended that all steam pipes to air pumps, injectors, etc., be insulated with asbestoc from 1/4 in. to 1/2 in. thick, depending upon the amount of room around the pipe then covered with asbestos canvas, which in turn is covered with retort cement, thus making a weather and heat proof job. This applies to steam piping in the cab.

There is about 50 sq. ft. of uninsulated surface around the water legs of nearly all locomotives, which could be insulated with very little trouble to assist in preventing some of the per cent loss in radiation.

Stoker equipment should receive thorough attention while in the shop. One particular part of the stoker equipment which has caused considerable waste of fuel is the conveyor trough underneath the deck. When the conveyor is working, coal is pushed over the top of this trough and thrown on the ground. Inspection develops that this condition still exists and it should be eliminated.

An apparently simple matter but one which causes a waste of fuel, is the condition of the deck around the grate levers. It is common to find large holes around these levers through which coal is constantly lost while the engine is in service. In the first place, such holes should not be cut in the deck, but if they do exist, they should be covered with strips of metal.

Where the air pump exhaust is tapped into the smoke arch and goes out through the smoke stack, this connection should be changed to the exhaust passage in the saddle. There are two reasons for this: one is, that the exhaust passing through the front end creates a draft on the fire which cannot be controlled by the engineman and wastes considerable fuel; the other is, that as the air pump is usually working more or less, the exhaust from the pump will assist in relieving a vacuum in the exhaust passage when the throttle is closed and the train moving, which in turn reduces the amount of soot and gases drawn from the front end into the cylinders.

It will be impossible to touch on the general overhauling of the locomotive, but the parts and devices mentioned have been dwelt on because they have a direct influence on fuel consumption. It is true that they can be neglected and the engine will get over the road, hauling the train and apparently none the worse for the neglect. While it may not be visible in the operation of the locomotive, lack of repairs to these parts does waste fuel. As this waste is preventable and is no doubt many times greater than the cost of making repairs, we do not hesitate to recommend that such repairs be made.

It is easier to win when you are in the lead than to catch up when you get behind. The habit of starting early and starting right is not acquired by any sudden resolve. It must be built by careful practice and steady training—by conscientious study with the application of the best rules

and regulations. Plan your work, then work your plan, making every play and every day a definite advance toward the goal, which should be 100 per cent locomotives.

Roundhouse Maintenance

In considering roundhouse maintenance, we must assume that the officer responsible for locomotive maintenance is allowed sufficient time to make necessary repairs. On nearly all railroads, the transportation officer often requires the turning of the power so rapidly that locomotives do not receive needful repairs. One superintendent told at a division fuel meeting that he was running his engines until the stack fell off and the bell rolled over into the field. In starting engines out in this condition, he realized that they were not fit to go but gambled that they might make a successful trip. His testimony was that he often had to send a second engine to get the first one in.

Sooner or later, locomotives have to be repaired, and under the present operating conditions we cannot look forward to a slump in business which will make it possible to hold power in the roundhouse long enough to do work on them which has accumulated. If the mechanical officer is successfully to maintain the locomotive in condition for economical and successful service, "the stitch in time" rule must be put into effect. This means that repairs have to be made as the need for them develops. He should be the judge of when a locomotive is fit to leave a roundhouse ready to make a successful trip. Often locomotives are hurried out and fail, necessitating the use of a second engine which many times has to give up a train of inferior class to take a superior train to a terminal. Such practices cause delays and congestion on the railroad and could be avoided generally if locomotives received necessary repairs.

As in the shop, we will consider the maintenance of the boiler and firebox as the first consideration. The boiler should be kept clean by frequent and thorough washings, preferably with hot water. It is generally accepted that hot water wash-out plants materially reduce the time required to wash boilers and by using waste steam to heat the water used for washing and filling, a direct fuel saving is accomplished.

It is important that sufficient pressure be used, with nozzles so designed that the water will reach all parts of the boiler. With well located wash-out plugs, it will then be possible to thoroughly clean the boiler at each wash-out. This, of course, implies that where water contains scale-forming elements, some form of water treatment be used.

In a paper by A. N. Willsie, read at the International Railway Fuel Association meeting, May 15, 1916, he shows a table giving the loss of heating power due to scale as follows:

"There seems to be a variance of opinion as to the losses due to the accumulation of scale in boilers. Some of the best authorities give the losses as about as shown in the following table:

APPROXIMATE LOSS OF HEATING POWER DUE TO SCALE

Thickness of scale, in.	1/64	1/32	1/16	1/8	3/16	1/4	3/8	1/2	5/8	3/4
Per cent loss of heating power	2	4	9	18	27	38	48	60	74	90

"These figures are not considered absolutely accurate as these losses are not found to occur in all boilers because the whole of the boiler surface does not usually become covered; still the loss is always serious, apart from the stresses set up in the boiler plates.

"The test made by Mr. Breckenridge of the University of Illinois, on a Mogul freight engine, which had been in service for 21 months, is recorded in the *Railroad Gazette*, January 27, 1899, page 60. This engine was tested, then sent to the shops and new flues installed, then tested the same as before. In order to get the average thickness of

scale, it was entirely removed from the tubes and weighed. This thickness gave an average of 3/64 in. on the principal heating surface and the loss in heating power due to the scale was 9.55 per cent."

It is evident that there is a decided loss in heat transmission when boiler sheets are allowed to accumulate a scale deposit. Water treatment and thorough boiler washing will practically eliminate scale from locomotive boilers in any kind of water. When boilers are kept clean it is comparatively easy to maintain the flues free from leaks.

There should be an inspection of the flues each trip and where necessary, they should be calked, or expanded and calked, depending upon the practice standardized on each railroad. Where flues are welded in, welding outfits should be maintained at terminals so that when the welds break, they can be re-welded. Firebox leaks, even though they do not cause failures, waste fuel, and where locomotives are allowed to run with flues in a condition that causes failures or near-failures, an excessive amount of fuel is consumed per trip. Flues which will not permit a successful trip should be changed.

Grates should be renewed when fingers are broken or burnt off and grate bars should be well maintained, insuring a perfect support for the grate sections. Grates should shake freely. To make this possible, grate levers and rods should be kept in good working condition. Grate fingers should not bind. Any neglect in the maintenance of any part of the grates or shaking apparatus tends to discourage the intelligent use of grates by engine crews and on this account should be thoroughly maintained. Steam grate shakers should be kept free from steam leaks at all joints in the piping and the grates otherwise maintained the same as with manually operated grates.

Frequent inspections should be made in the front end. The front end inspector should have someone on the outside open and close the superheater damper and actually see that the damper opens full width, not moving on the damper shaft. Where engines are equipped with petticoat pipes, the pipes should be renewed when worn and set to insure exhaust jet going out the center of the stack. Inspection should show that the locomotive still has the standard size nozzle with which it came from the shop.

When reports are made that the engine does not steam, do not make any change in the draft appliances. The steam pipes should be subjected to a hydrostatic test to determine whether there are any leaks in the superheater elements or return bends, steam pipes, at the base of nozzle stand, or at the base of the nozzle tip. If everything is tight and set to the adopted standard, someone should ride the engine to locate the trouble. Find the real trouble; do not change appliances or reduce the nozzle, except for weather or special fuel conditions.

It should be known by inspection that flues, both on superheated and non-superheated locomotives are kept clean. Nearly all roads have flue cleaning organizations but it has been found necessary to check up the work of these men to insure their doing it thoroughly. The Fuel Conservation Section has issued circulars showing the loss in fuel due to stopping up of large flues on superheated locomotives. This loss varies as shown on the following table from Circular 16:

Number of superheater flues stopped up.	Average temperature of steam (deg. F.)	Drop in temperature below 586 deg. F. (deg. F.)	Superheat (deg. F.)	Fuel loss (per cent.)
None	586	..	211
5 to 7	576	10	201	0.04 to 2.6
8 and 9	549	37	174	6.0 to 9.6
12	517	69	142	13.2 to 14.6
18	491	95	116	21.0 to 24.2

If, for any reason, valves become out of square through lost motion in the valve gear or accident, they should be squared up immediately.

Cylinder and valve rings should be renewed when necessary to prevent blows, which are exceedingly wasteful of steam and materially affect the hauling power of the locomotive. Many roads have adopted a 30-day inspection of cylinder and valve rings. Such inspection develops many worn rings which would not be reported. This practice is recommended for consideration by roads not doing it. If an engine has been out of the shop for a long time and the cylinders have become worn 1/8 in. or more, they should be re-bored and fitted with packing rings turned to fit the re-bored cylinders, such rings being maintained in stock.

Hot-box reports should receive prompt attention. If a locomotive is equipped for the use of water on hot bearings developed en route, it should be known that there is no stoppage in the line of water travel to insure an available supply when the need arises. Water cooling equipment on locomotives should not in any way relieve the roundhouse from prompt attention to defects causing hot bearings.

A habit has prevailed to some extent which has been expensive wherever practiced. That is, allowing locomotives due for the shopping in two or three months to run with valves out of square, with cylinders blowing, leaky flues, or some defect which materially affects the successful operation of the locomotive. The money wasted due to not making repairs which would have permitted the economical and successful operation of the locomotive, would have been saved many times over while the engine was waiting to go to the shop.

All auxiliary devices, such as bell ringers, headlight dynamos, firedoors, steam grate shakers, power reverse gear, etc., should be kept in good repair. Many of them are put on the locomotive to increase the economy of locomotive operation and unless they are maintained, the effect is just the opposite.

No lost motion in power reverse gear levers and connections should be allowed and no air leaks in the piping should exist. If these two things are taken care of and the packing is well maintained, there should be little trouble from reverse gears creeping. Usually, the engineer is relieved from oiling the reverse gear and oftentimes this is neglected in the roundhouse, resulting in a dry piston, which means a slow acting gear.

Where flange oilers are used, the nozzle which feeds the oil to the flange should be in alinement with the flange and kept securely fastened there so that the oil will be deposited on the flange and not on the tread of the rail. A heavy, sticky oil should be used for flange oilers in preference to the lighter crude oils. This gives a longer wearing lubricant, materially assisting in the reduction of rail wear in addition to reduced flange wear.

Injectors should be maintained so that they will go to work without excessive attention on the part of the engine crew. One of the most annoying features with which enginemen have to contend is an injector which will not go to work unless fussed with for some time. This causes unnecessary safety valve operation and oftentimes an actual neglect of the fire, all contributing to a direct fuel waste.

Firedoors of the manually operated type should be evenly balanced, insuring ease of operation, equipped with a good latch on the door to hold it open when the track is rough or in going around curves. It is impossible to fire well if the door closes while the fire is being put in. The chain should be hung so that the firemen can reach it and open the door with a minimum of effort. In fact, he should be able to open the door and close it between each scoopful of coal fired, hardly knowing that the door is there.

Safety valves should be coordinated with the steam gage so that the blow-back should not be more than three or four pounds.

The apron between the deck of the locomotive and the

shovel sheet should be level. An apron which is curved or bent in any manner makes it difficult for the fireman to stand securely while firing. To enable the fireman to practice skillful firing, there should be no hindrance to a full, easy play of the muscles. Bent or curved aprons and roughed shovel sheets hamper the smooth work of a fireman materially. The shovel sheet should be level and free from any obstructions which will interfere with the movement of the shovel over the sheet and should extend back far enough into the coal to allow the fireman to get practically all of the coal out of the pit. A coal guard should be placed in the right gangway to prevent coal from being pushed out.

Brick arches should be maintained as shown by standard instructions.

Steam leaks around the locomotive are not only a Federal defect but are wasteful of steam.

The air brake system on the locomotive should be maintained free from leaks, and the compressor should be in as near 100 per cent condition as possible. The loss in time necessary to charge trains with the accompanying loss in fuel through steam consumed when the compressor is in poor condition is illustrated by the accompanying table from Mr. Willsie's paper, mentioned previously:

"The actual number of cubic feet of free air compressed to 100 lb. per minute pressure with 200 lb. steam by several compressors is as follows:

Compressor	100 per cent condition	75 per cent condition
9½-in.	44 cu. ft.	33 cu. ft.
11-in.	66.5 cu. ft.	50 cu. ft.
8¼-in. C. C.	131 cu. ft.	97.5 cu. ft.

"The 100 per cent condition referred to is the capacity of the air end of the compressor when in perfect condition, and is necessarily considerably less than the actual displacement of the compressor air piston.

"The 75 per cent condition referred to is the minimum condition permissible under the Interstate Commerce Commission ruling, and relates to the 100 per cent condition first mentioned."

It is necessary to use a drifting throttle on superheated locomotives to insure good lubrication. If a drifting throttle is to be used, we should provide the engineer with a throttle that will stay set in any position desired. Many throttles of necessity are shut off entirely or are nearly wide open and the engineer has to use a stick or try and hold the throttle in a drifting position, which is practically out of the question.

Engineers must be encouraged to make out the necessary reports for the guidance of the roundhouse foremen in maintaining the locomotive. A locomotive inspector, preferably an engineer, who would meet incoming engines while the crews are still on them, talk with the crew about the locomotive performance, help them make necessary tests to determine blows, etc., assist the engineer in making out his report, possibly making out a separate one, and then check the work done on the locomotive when it comes out of the roundhouse, can be of untold value to any mechanical organization, as these men not only uncover many defects but help educate the engineer to make out intelligent work reports, saving the mechanics considerable time in hunting for defects.

Terminal Handling

After the actual mechanical work of preparing the engine for service has been finished, we are going to assume that the transportation officer is cooperating with the mechanical officer, making it feasible to place a definite order for the locomotive for a certain time. Definite printed instructions should be posted in every roundhouse showing just how far in advance of leaving time, each class of power should be fired up and just how the fire should be built. The fire builders should follow this line-up.

To prevent pops opening in firing up, the blower should be shut off before the maximum steam pressure has been

reached. This, of course, implies that the instructions to the fire builder provide against any heavy firing which would have built up too heavy a fire before leaving time.

When air brake men come around to test the air pump and brakes, they should not put more coal in the firebox and run the pressure up to the maximum, going away and leaving the pops blowing indefinitely.

Too many times when the fire is built an excessive amount of water is put into the boiler. When the engine is taken out of the house and placed on the storage track so full of water that it is impossible to work the injector any more, there is bound to be an excessive operation of the safety valves. When the engine crew arrive and the boiler is full, it is impossible for the fireman to build up the right kind of fire without the loss of a great deal of fuel through the safety valves. The boiler should be filled with sufficient water to prevent any danger of low water before steam pressure enough is obtained to work the injectors. The fire should be built up gradually, using just enough fuel to raise the temperature high enough to make all necessary tests before the engine goes into service.

From 20 to 30 per cent of the total fuel consumed by the locomotive is used around terminals, and there is room for real economy in the building of fires, if it is systematically supervised.

After the fire is built and the engine taken out of the house, just enough fire should be maintained to keep water enough in the boiler to provide against low water. With the boiler supplied in this manner, it is possible for the fireman to build up a fire of the right depth without excessive popping.

Hostlers should be taught by demonstration the way the fire should look when the engine is taken out of the roundhouse and inspection should be made of every fire before taking the engine out of the house. When poor fires are being built a report should be made to the roundhouse fireman to prevent a continuance of such practice. Lack of attention to fire building, resulting in poor fires being turned out of the roundhouse, has been responsible for many delays due to cleaning fires between terminals.

Cylinder cocks should always be opened and the engine started slowly when being taken out of the house or moved around the terminal by the engine watchman or hostlers. The cylinders nearly always contain water, and unless the cylinder cocks are open and the engine moved slowly, this water is worked directly through the cylinder and out through the stack. The writer is of the opinion that a great many of our cylinder leaks are caused by working water through the cylinders around terminals.

When engines are placed on the outgoing track, all tools and oil cans should be on the engine in good condition so that the crew will not have to run around looking for supplies, which takes time away from their regular duty of preparing the locomotive. Incoming locomotives should be dispatched with the greatest possible speed to insure all of the time possible in the roundhouse for necessary work. If the roundhouse is too small to handle the business, it is better to take out the engine which has been repaired and make room for an incoming engine needing repairs than to keep the incoming engine outside for several hours and then, when it is in the house, have to turn it out again without having time to do the necessary work.

Many different local conditions handicap thorough mechanical repairs. I remember an instance last winter on a certain railroad where we found the superintendent and master mechanic cleaning fires on the cinder pit to assist in moving power through the terminal. It is obvious that many things which have been suggested in this paper will be lost sight of under such conditions, but we must have high ideals or our general practice will be of a low standard.

NEW DEVICES

A 14-INCH GEARED HEAD LATHE WITH COMPACT MOTOR DRIVE

A new 14-in. geared head lathe with a compact arrangement for motor drive has been placed on the market by the Reed-Prentice Company, Worcester, Mass. It is a well balanced machine and the distribution of metal is apportioned to absorb vibration under heavy cutting feeds and speeds. In casting the various units an equal thickness of walls was maintained so that when cooling undue internal strains would not develop, and distort the machine after delivery.

The lathe headstock is of the selective type, permitting the operator to obtain any one of eight speeds without slowing down the machine or removing the cutting tool from the work. It is stated that the change from one speed to another cannot

a plane with the pulley shaft, permits more rigid construction of the shipper mechanism and a more accessible arrangement for adjusting the friction fingers when necessary.

In order to remove the face plate from the spindle nose, a locking mechanism has been introduced in the form of a plunger which engages the hardened steel notched ring, keyed directly to the spindle. This prevents the rotation of the spindle and permits the removal of the face plate without transmitting any strain to the gear teeth. To insure against starting the spindle while this plunger mechanism is in operation, a locking mechanism has been introduced which prevents the engagement of the spindle clutch until the plunger has been removed. In case the clutch is engaged, the locking mechanism also keeps the plunger set at neutral position.

A geared pump in the headstock supplies the lubricating

Reed-Prentice 14 In. Geared Head Lathe with Driving Motor Located Inside the Cabinet Leg

be detected on the work even should such a change be made while the tool is taking a cut. The speeds are obtained by the use of spur gears which are constantly in mesh the full width of face and depth of tooth. The internal expanding friction clutches are of special patented design. It is impossible to engage conflicting ratios of gears as the spindle will not start until the three levers are in operative position. Therefore, any one of the levers when brought to a neutral position will at once stop the spindle. The spindle bearings are hardened and ground. The journal boxes are of bronze, scraped to the spindle to insure correct alignment and maximum bearing surface.

The back gears, spindle and pulley shaft have been brought up to the same plane which makes them much more accessible and permits the gears to run in an oil bath. The intermediate bevel gear in the reversing attachment being brought up to

oil for all of its bearings, with the exception of the two main spindle bearings, which are supplied from sight feed oilers as shown. Ball bearings of the Gurney type are used in the drive pulley, which eliminates most of the friction due to belt tension. The rocker carrying the tumbler gears at the end of the head is of new design, being a pull plunger with locating holes in the side of the head. The spindle is reversed by means of bevel gears and shafts in preference to the old link motion. The control handle for the stop, start and reverse is located at the right hand lower corner of the apron and is therefore at all times in a convenient position for the operator. The quick change gear of this lathe has also been modified to make the entire unit more accessible and rigid.

The carriage apron is of double plate construction, which permits easy access to the internal mechanism without removing the carriage from the bed. The shafts and studs are sup-

ported at both ends in bronze bearings. The rear plate is made in box form securely bolted to the carriage. The open-and-shut nut works in guides which are cast integral with the rear plate. A new locking mechanism, simple and rigid in construction has been incorporated to prevent the engagement of the longitudinal feed when the open-and-shut nut is engaged and vice-versa. An oil reservoir with protecting dust cap is placed at the upper right hand corner of the apron for lubricating all of the bearings in the rear plate. The front bearings are lubricated by oilers provided at each bearing.

The carriage has an exceptionally large area over the

Rear View of Apron Showing Double Plate Construction and Feed Bevel Gear Arrangement

sliding surfaces on the vees of the bed. The bridge does not extend by the front horns, this being overcome by widening the apron seat. The tailstock has been strengthened and made more rigid by widening the base and giving it a better support on the inside vees of the bed. The additional vee in the tailstock has a reinforcing effect on the bed, acting as a clamping device wherever the tailstock is located.

The bed has been not only widened and deepened considerably, but reinforced throughout by increasing the metal thickness and spacing the heavy ties much closer together. The top of the bed is of the drop vee type, the inside vees

Back Gears, Pulley Shaft and Spindle are all in the Same Plane

being lower than the outside, thereby preventing any excessive cut in the bridge of the carriage.

Slight improvements have been added to the taper attachment, particularly in the method of guiding the traveling shoe on the taper bar. There has always been a tendency of the shoe to lift from the bar when under pressure, which had a slight effect on the work. This has been eliminated by the introduction of a gib engaging a ledge planed the entire length of the taper bar. Graduated dials, reading in the thousandths of an inch, are made a part of the rest screw. When the lathe is belt driven directly from the main line or

countershaft, standard cabinet legs are used, having doors in the front so that the space inside may be utilized for storage purposes. The steel oil pan with oil reservoir pump and piping are furnished when ordered.

Two types of motor drive can be furnished. In the one illustrated the motor is mounted inside the head-end cabinet leg and connected to the head drive shaft by a carefully guarded belt or silent chain. This arrangement is compact, protects the motor and eliminates the overhang of motor or pulleys. The second method of motor drive is through rawhide spur gears with the motor mounted on a bracket at the rear of the machine. The bracket is bolted to a pad cast integral with the head end cabinet leg.

HEAVY DUTY CRANK SHAPER

A 16-in. heavy duty back geared crank shaper has been developed recently by the Streine Tool & Manufacturing Company, New Bremen, Ohio. The base of this shaper is of the extended type, unusually deep and affords a solid foundation for the machine. T-slots in the large planed

Stamco 16-in. Heavy Duty Shaper of the Extended Type

surface run back to the column, as shown in the illustration, and provide for setting up large pieces of work. The rigid construction of the machine throughout renders it suitable for the heavy work usually found in railway machine shops.

The column is of unusual depth and width at the base, thus making a more rigid joint between the base and the column, and at the same time lowering the center of gravity. The bull gear bearing is cast solid in the frame, which eliminates considerable wear caused by springing and friction. The bull gear itself is supported close to the rim by the frame which does away with the tendency for it to bind or break away from the hub. The total area of the bull gear bearing is 205 sq. in.

The crank block and its adjusting mechanism are set into the bull gear, thus reducing the overhang between the rocker arm and the gear to a minimum. The bull gear construction and its relation to the rocker arm, as mentioned above, eliminates practically all vibration and chatter, without making the working parts too heavy and cumbersome.

The bull pinion rotates on bronze bushings as in the

usual planer construction, and the intermediate gears are mounted on extended hubs of the pinion. The driving gears are mounted on a long sleeve, which slides on a key in the pulley shaft. The gear ratio is arranged so that the speeds of the ram are in geometric progression and there are no conflicting gear ratios as in some forms of pinion gear drive. The pulley rotates in a sleeve bearing bolted to the column, thus relieving the shaft of belt pull and eliminating an extra bearing. An unusually long ram bearing is provided, which insures accuracy and reduces wear to a minimum. The rail is clamped to a dove-tail slide on the column, insuring accuracy in any position. The saddle fits into a narrow guide on the rail, which provides large wearing surfaces and equalizes the strain on the rail screw. The position of the table is controlled by means of a telescopic elevating screw, which is provided with a ball thrust bearing. The table can be removed, as previously stated, and large work bolted to the saddle or base.

Arrangement is made to vary or reverse the feed while the machine is in motion, and the feed can be set at any desired amount quickly. Owing to the absence of adjustable or friction links the feed is constant at any position of the rail. The adjusting screws are provided with micromoter collars, graduated to .001 in. and all adjustments are within easy reach of the operator. The head and the vise are graduated in degrees and can be set to any angle.

The shaper has an effective stroke of 17 in. with a cross feed of the table of 24 in. The vertical table feed is 15 in. and the greatest distance of the table to the ram is 16 in. The feed of the tool is 7 in. and the diameter of the head 8 in. The number of strokes per minute may be adjusted from 6 to 120.

TRAVELING WALL CRANE

The traveling wall type of crane has proved its value in the satisfactory solution of handling problems in many plants. Used as an auxiliary to the overhead cranes, it avoids delays and congestion and leaves the overhead cranes free for heavier loads and longer runs. The crane shown is

channels, beams, plates and angles, combined in a rigid structure. Truss rods or eye-bars give stability to the boom. Two motors connected in parallel and operated through one controller are provided for the longitudinal travel. The motor pinion engages directly into the driving gear which is pressed and keyed onto the double-flanged cast-steel truck wheel. The thrust wheels at the top and bottom are turned from solid cast steel blanks. A foot brake operated from the cage is provided to effectually control the longitudinal travel and to stop the crane without the necessity of reversing the motors. The brake is of the band type, the brake wheel being mounted directly on the armature shaft of one of the motors. The operator's cage, made of structural steel with a plank floor, is of sufficient size to contain all controllers, the switchboard and resistance, and still leave ample room for the operator. When desired the cage can be omitted, rope-operated controllers provided and all operations can then be accomplished from the floor. With the floor-operated type the foot brake is omitted and a solenoid brake provided, the latter being attached directly to one of the driving motors. A bumper bar and rail checks are provided at the end of the boom.

The hoisting mechanism consists of a one-piece cast frame on which is mounted the hoisting motor with its train of gears, the solenoid brake and hoisting drum. The gears are of cast steel. All pinions are of forged steel, machine cut and fully enclosed. The bearings are phosphor bronze, of the split shell type, the grey iron bearing caps being held in position with through bolts. The shafts are turned and ground to size from open hearth steel bars and shouldered to prevent excessive end play. Gears and pinions are keyed and pressed onto their shafts. The hoisting cable leads from the drum through one set of idler sheaves on the trolley, through the bottom block sheaves, then through the second set of sheaves on the trolley and is anchored at the end of the boom. The solenoid brake performs two functions. It serves to stop the motor, thus providing for rapid reversal, and it also acts as a holding brake when the load is brought to rest through the dynamic braking control. The brake wheel is mounted directly on the extended armature shaft,

Traveling Wall Type Crane In a Longitudinal Shop

designed and built by the Toledo Bridge & Crane Company, Toledo, Ohio. The four-motor type drive is used and arrangements can be made for either direct or alternating current motors. The crane is regularly furnished in capacities of three and five tons and for an effective reach up to 30 ft.

The back framing and the boom consist of rolled steel

and is accurately machined and balanced. The brake is automatic in operation, and is so arranged and connected that should the supply of current fail or the controller be brought to the neutral or off position, the brake at once becomes operative, prevents the load from falling or slipping and is released only by the application of power or by spread-

ing the brake arms against the tension of the springs. When alternating current motors are used the hoist motor is provided with a solenoid brake and the standard band type of mechanical brake is applied. This brake is of the screw friction type, automatic in operation, and the load can be lowered only by operating with power in the lowering direction.

THE ACME FLANGED LOCOMOTIVE TENDER TANK

A locomotive tender tank formed of flanged steel plates is being placed in service on a number of large railroads by the Locomotive Tank Company, New York.

The special feature of this tender tank, which is known as the Acme flanged tank, is the flanging of the edges of the plates inwardly and riveting them together inside of the water space instead of on the under side of the tank, where

center section or pan is directly under the water intake and tends to retain in it such pieces of coal, cinders and sediment as might pass through the screen and if carried on with the water would interfere with the operation of the injectors.

It is stated that the tests to which this tender tank has been subjected and the record of costs for material and manufacture indicate that it will prove to be a very economical method of locomotive tender construction.

PNEUMATIC MILLING MACHINE VISE

A milling machine vise, so designed that it can be operated by air or used as an ordinary hand-operated vise, has been placed on the market recently by the American Pneumatic Chuck Company, Chicago. This vise is made so that it may be placed either crosswise or lengthwise on the table of the machine. No part extends above the jaws which hold the work, so the cutters can pass over the entire vise. The

Acme Flanged Locomotive Tender Tank Showing the Accessibility of the Riveted Joints

the rivets are difficult of access in case of leakage requiring repairs. Repairs can be made to the bottom of this tank without raising it from the frame, as all of the riveting is done on the inside. This feature not only reduces the cost

design follows the modern standard milling machine vise in the construction of jaws, screw slide and tongues and slots. The body is made of a steel casting and the entire construction is substantial and rigid. The adjusting screw slide is built into the body of the vise, becoming practically a part of it. It is claimed that this vise is economical in the use of air due to the fact that after the piece of work has been gripped by the jaws, the air supply may be shut off entirely without the jaws loosening up.

The power required to hold a piece of work in any vise is greater than usually realized, and this milling machine vise

Comparison of Acme Flanged Joints with the Old Type Joints

of repairs, but as the flanged portion of the plates provides a means of riveting them together, a great number of the angle irons and rivets required in the older types of tender tanks are eliminated.

Other advantages of this type of construction are that no rivets or holes pass through the top or bottom of the plates and the bottom of the tank sets firmly and smoothly on the tender floor, thus evenly distributing the strains. The absence of angle and T-irons and sharp corners in the interior of the tank also prolongs the life of the bottom. The

Air or Hand Operated Milling Machine Vise

is fitted with a 4-in. air cylinder, which with 80 lb. pressure on the piston gives a total pressure of about 1,000 lb. By means of a toggle joint arrangement on which patents are pending, this initial pressure is increased by more than 30 to 1, which, making allowances for friction, etc., gives a final gripping power at the extreme point of movement of the

piston of about 25,000 lb. pressure on the work. While the vise is capable of exerting this heavy pressure, it is claimed that the jaws can be adjusted so that the most delicate work can be held without crushing it. The double acting air cylinder opens and closes the jaws practically instantaneously, but they can be so regulated as to travel slowly towards the work. The air valve is mounted directly on the cylinder and requires only one hose connection.

HEAVY UPSETTING FORGING MACHINE

The steady increase in the use of alloy and high carbon steels in forging has created a demand for heavy forging machines to stand up under the increased strain of working these materials. Accurate, economical, high production is also desirable and the upsetting forging machine illustrated has been designed by the Ajax Manufacturing Company, Cleveland, Ohio, to include all of the above qualities. The machine weighs 12,000 lb., which is about 40 per cent heavier than the old 4-in. model. The steel bed is reinforced with tie rods. The crank shaft bearings in the continuous housing of the bed are of the sleeve type, phosphor bronze bushed, and the steel gears and pinions are especially treated with teeth cut from solid blanks. The positive die grip is protected by a breaker bolt in the safety knuckle, the latter being operated by a patented lock device which stops the dies in the wide open position and stops the header slide at the back of its stroke.

The capacity of the new forging machine has been demonstrated in tests recently conducted at the Cleveland plant. It is stated that a 4-in. machine, in a single blow, forged a disk 9½ in. in diameter and 1¼ in. thick on the end of a 3½-in. bar of steel of .60 carbon content at a cherry red heat.

grooves in the gripping dies. The die slide carries the moving die in a box shaped recess which gives substantial support against the backing plate during the heading operation. Local wear in the backing plate and the resulting tendency of the die slide to rock is thus eliminated. In order

Rear View, Showing Twin Gear Drive

to transmit the power necessary for the making of large forgings, a twin gear drive from the pinion shaft to the crank shaft is employed on all machines of the larger sizes. This gives equal torque to both ends of the crank pin, greatly decreasing the strain in this part. In addition, the crankshafts have been nearly doubled in weight.

The self-adjusting safety pitman, the construction of which

New Model Forging Machine Designed for High Production

In doing this eight inches of stock were gathered and flattened out without stalling the machine.

The slides are considerably increased in length and operate on overhung bronze faced bearings, thus preventing undue wear by the accumulation of scale and dirt on the sliding surfaces. Arrangement is made for ample lubrication. The header slide carries a triple-high tool holder, so constructed as to permit its adjustment to any desired location of the

is shown in the photograph, is a new feature. The middle center is slightly raised above the line of the other two so that a pressure on the ends results in a buckling tendency. This buckling is resisted up to a predetermined pressure by the latch held in place by the heavy coil spring. When the limiting pressure is reached the latch jumps up, giving complete relief without the building up of additional pressure. On the return stroke the pitman straightens out, the

latch drops into place and the machine is ready to go on with its work with no delay. By tightening or loosening the spring a nicety of adjustment can be obtained which permits the working of the machine to its full capacity with assurance that the limit of its strength will not be exceeded. Machines equipped with this type of pitman have been in operation continuously for the past three years and have been giving a satisfactory performance under the most severe service tests.

In order to increase the capacity of the machine to corre-

Safety Pitman in Operating Position and Sprung by Excessive Pressure

spond to its increased power and strength, the stock gather, die opening and die height have been greatly increased. The production of larger forgings in fewer operations is thus made possible and the additional space for the placing of more grooves in a single face of the die reduces the number of die changes necessary. The machine is made in 4-in. and 5-in. sizes.

PARALLEL RULER ATTACHMENT

Several advantages result from the use of a parallel ruler attachment with a drawing board, one of the most important being the saving in time previously spent by the draftsman in watching the head of his T-square. The attachment shown herewith is more accurate than the average T-square and in addition can be adjusted at any required angle across the drawing board by means of the thumb nuts on the binding post.

This parallel ruler has been placed on the market by the Economy Drawing Table Company, Adrian, Mich. It consists of a set of two double pulleys *A* attached to the back corners of the drawing board, and two single pulleys *B*, attached to the front corners. A steel piano wire *C* is placed around these pulleys, making a double lap along each end

and back of the board. By crossing the wire at the back the upper laps at both ends must move forward and back simultaneously. The ends of the wire are joined together at the back by a steel spring *D*. Both ends of the straight edge are attached to the upper wire at the ends of the board by binding posts *E*, thus making it possible to move one end of the straight edge without moving the other a corresponding amount in the same direction. All pulleys, brackets and

Economy Parallel Ruler Attachment Applied to Drawing Board

binding posts are made of brass accurately machined, polished and lacquered. The attachment is accurate, as both ends of the straight edge are attached to the same wire and can be moved back and forward only simultaneously. The straight edge can be lifted clear of the board for changing drawings without loosening any thumb nuts, and can be set at any angle across the board by thumb nuts on the binding posts. The entire arrangement is simple, durable and easily applied.

BOYERGRIP FOR PNEUMATIC HAMMERS

The Boyergrip is a device recently brought out by the Chicago Pneumatic Tool Company, Chicago, which combines a convenient hammer grip with an absolutely safe set retainer. As shown in the illustration, it fits over the end of the riveting hammer and enables the operator to secure a firm grip without grasping the heated cylinder. This arrangement makes the operation of the hammer more convenient and allows the workman to drive hot rivets without

Combined Hammer Grip and Set Retainer

danger of burning his hands. The device also provides an unobstructed view of the work from all angles. The Boyergrip is made of steel and is practically indestructible. A modified form of this device, which is well adapted for use on chipping and calking tools has also been placed on the market.

In an effort to encourage more skilled workmanship the Canadian Pacific inaugurated a competition among apprentices at the Angus shops, and the five winning pupils were recently presented with prizes of books by James D. Muir, assistant works manager, at a gathering presided over by C. Kyle, supervisor of apprentices. There were present about 423 apprentices and Mr. Muir pointed out to them that it was only by diligent work that advancement to a marked degree was attained, and that full interest in their tasks was a necessity. Others who spoke were J. R. Ayers, general master painter; E. T. Spidy, production engineer; John Kennedy, piece work supervisor; Charles Bulley, class instructor of the apprentices, and J. W. Wood, shop instructor.

The rumor reported in the January issue that the Ministry of China has engaged four foreign experts to assist in the standardization of rolling stock is now abundantly confirmed by the arrival of these gentlemen in Peking. One is Frank H. Clark, formerly superintendent of motive power of the Baltimore & Ohio. The others are T. R. Johnson, formerly commissioner of railways, New South Wales, and latterly engaged in consulting work in London; M. Taton, personal representative of M. Painlevé, formerly Minister of War, France, who was engaged by the Ministry, but is unable to come at present, due to political conditions in France, and Dr. Hirai, the present Japanese Adviser to the Ministry. In addition to the standardization of rolling stock, this group will attempt to standardize signal practice, bridge dimensions and other maintenance practice.

In an article on the transport and coal question in the *Börsen Courier*, quoted in the *Railway Gazette* (London) a leading German manufacturer of locomotives says: "It might appear that the German locomotive industry is specially interested in receiving orders from the State Administration. The opposite is really the case. In the large locomotive works in Germany new locomotives are being built, mainly out of pre-war material, and production in the workshops has increased that it may be said to have reached the peacetime standard. The Hanoverian Maschinfabrik, for instance, is at the present time building some 32 new locomotives monthly, with the employment of 5,000 permanent workers. Having regard to the present economic situation in Germany, the only strange fact about this is that these lo-

Subscriptions, including the eight daily editions of the *Railway Age*, published in June, in connection with the annual convention of the American Railroad Association. Section III—Mechanical, payable in advance and postage free: United States, Canada and Mexico, \$2.00 a year; Foreign Countries, \$3.00 a year; Single Copy, 20 cents.

WE GUARANTEE, that of this issue 12,000 copies were printed; that of these 12,000 copies, 10,803 were mailed to regular paid subscribers; 20 were provided for counter and news company sales; 219 were mailed to advertisers; 33 were mailed to employees and correspondents, and 925 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 24,200, an average of 12,100 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. P. C.).

comotives are all sold to foreign countries. The prices which foreign countries are offering for German locomotives are such as to enable the manufacturers to provide themselves with all kinds of material, not only machinery, oil, etc., but also coal either from Germany or abroad."

The Brotherhood of Maintenance of Way Employees and Railway Shop Laborers has bought four clothing factories, and promises to reduce prices from 25 to 60 per cent. The factories include knitting and underwear companies at Ypsilanti, Mich., a glove factory at Williamston, Mich., and a tubing factory, making tubes used in gloves, in Watertown, N. Y. Unverified reports of such action have been in circulation since the authorization of such a campaign at the national convention of the brotherhood in Detroit, Mich., in September, 1919. The present report has been confirmed by officers of the brotherhood, who announce that the purchases thus far consummated represent an initial investment of approximately \$1,000,000 and are "but the first steps" in a campaign to reduce the cost of living for members of the brotherhood. It is proposed to sell to the members of all railway brotherhoods.

North British Railway Changes

W. P. Reid, locomotive superintendent of the North British Railway, retired from active service at the end of December. Mr. Reid started his railway career in 1876 under the direction of Dugald Drummond, then locomotive superintendent of the North British railway, at the Cowlairs works. In 1883 he was placed in charge of the locomotive depot at Balloch, in 1889 he was removed to Dumfermline, in 1891 to Dundee, and in 1900 to St. Margaret's depot, Edinburgh, which is the second largest locomotive depot on the North British railway system. It was in 1904 that he was made locomotive superintendent of the North British railway.

Owing to the retirement of W. P. Reid, the position of locomotive superintendent will be divided, and Walter Chalmers, the present chief draftsman at the Cowlairs works, Glasgow, will become chief mechanical engineer with charge of all workshops and dock machinery, while the position of locomotive running superintendent will be taken by John P.

Grassick, at present district locomotive superintendent at the Eastfield depot. The headquarters will be at Cowlairst, Glasgow.

Mexico to Spend \$2,000,000 for Equipment

An appropriation of 4,000,000 pesos, equivalent to \$2,000,000, has just been authorized by the Mexican government for the purchase of rolling stock for the National Railways of Mexico. Most of the new equipment will be second-hand and will be purchased in the United States. There is at present such a shortage of cars and engines upon the different divisions of the National Railways that it is impossible to move but a small percentage of the traffic that is offered. Thousands of box cars have been wrecked by bandits and revolutionists during the last several years. The shops of the railroad at Saltillo, Aguas Calientes and other points are doing considerable work in the matter of reconstructing damaged cars and engines, but the number which is being turned out is far from sufficient to meet the demands of traffic. Thousands of new railroad crossties are needed to repair the rundown condition of the system. Large orders for materials have been placed in the United States and some shipments of crossties have been received. In the more isolated parts of the country where timber is scarce the sidetracks have been torn up by poverty-stricken natives and the crossties used for fuel.

Standard Cars and Locomotives

Up to January 20, 92,412 of the 100,000 standard freight cars ordered by the Railroad Administration in 1918 had been delivered, leaving 7,588 to be completed. Of the total, 12,680 were built in 1918 and 77,423 in 1919. All of the standard locomotives will have been delivered by the end of January, but 11 Mikados of a special order placed for the Central Railroad of New Jersey are scheduled to be delivered in March.

Most of the locomotives which the Railroad Administration has been using during the period of federal control on roads other than those of their owners have now been "unscrambled" by being returned to their owners. According to a recent report there were still 515 locomotives off their own lines, of which 95 were in the Allegheny region, 66 in the Central Western region, 135 in the Eastern region, 49 in the North Western region, 15 in the Pocahontas region, 104 in the Southern region and 51 in the Southwestern region, but 236 included those whose location off line is a system affair over which the Railroad Administration need not concern itself. The location of 155 was required by public necessity and apparently they will still be so required to be off line on March 1. The location of 95 off line was at that time required by public necessity but there was some prospect of relocating it before March 1 either through termination of the necessity, by a rearrangement of equipment, or by repair of unserviceable equipment in shop. Only 29 locomotives were classified as being off the line for reasons not required by public necessity.

MEETINGS AND CONVENTIONS

Air Brake Association.—The twenty-seventh annual convention of the Air Brake Association will be held at the Hotel Sherman, Chicago, from May 4 to 7, inclusive. The Air Brake Appliance Association will have charge of the exhibits.

Material Handling Machinery Manufacturers' Association.—The convention of this association which was to be held at the Waldorf-Astoria Hotel, New York, on January 29 and 30, has been postponed, and will be held on February 26 and 27. Manufacturers from any part of the United States will be welcome, and especially makers of overhead cranes, hoists, conveyors, trucks, tractors and trailers. Reservations for the luncheon may be procured from Z. W. Carter, secretary, 35 West 39th street, New York.

American Foundrymen's Association.—The board of directors of the American Foundrymen's Association, at its annual meeting held in Cleveland on January 13, voted unanimously in favor of holding the 1920 convention and exhibit of the association in Columbus, Ohio, during the week of October 4. The exhibition buildings on the Ohio State Exposition Grounds will be used for the exhibits. In addition, adjoining buildings provide lecture halls and meeting rooms, making it possible to hold all the activities of the association in one place.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

- AIR-BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 163 Broadway, New York City. Convention May 4-7, Hotel Sherman, Chicago.
- AMERICAN RAILROAD ASSOCIATION, SECTION III.—MECHANICAL.—V. R. Hawthorne, 431 South Dearborn St., Chicago.
- AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.
- AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—R. D. Fletcher, Belt Railway, Chicago.
- AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 21, 1920, New Monterey Hotel, Asbury Park, N. J.
- AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
- AMERICAN STEEL THEATERS' SOCIETY.—Arthur G. Henry, Illinois Tool Works, Chicago.
- ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.
- CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 841 Laylor Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.
- CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—Thomas B. Koenke, secretary, Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
- CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—H. J. Smith, D. L. & W., Scranton, Pa.
- INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, C. H. & D., Lima, Ohio.
- INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. G. Crawford, 542 W. Jackson Blvd., Chicago.
- INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn.
- MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York. Convention May 25-28, Curtis Hotel, Minneapolis, Minn.
- MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION OF U. S. AND CANADA.—A. P. Dane, B. & M., Reading, Mass.
- NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Staler Hotel, Buffalo, N. Y.
- RAILWAY STOREKEEPERS' ASSOCIATION.—J. P. Murphy, Box C, Collinwood, Ohio.
- TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

PERSONAL MENTION

GENERAL

B. C. KING has been appointed assistant general boiler inspector on the Northern Pacific, with headquarters at St. Paul, Minn.

B. C. NICHOLSON, general foreman of the Denison locomotive shops of the Missouri, Kansas & Texas, has been appointed mechanical efficiency inspector, with headquarters at Parsons, Kansas.

F. K. TUTT, acting general master mechanic of the Missouri Pacific with headquarters at St. Louis, Mo., has been appointed mechanical superintendent of the Missouri, Kansas & Texas.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

F. A. BISSET, general foreman of shops of the Atlantic Coast Line at Sanford, Fla., has been appointed master mechanic at Waycross, Ga., succeeding J. E. Brogden.

C. A. CONNER has been appointed traveling engineer and trainmaster of the Green River division of the Denver & Rio Grande, with office at Helper, Utah, succeeding C. H. Wilcken, who has resigned.

F. A. O'NEILL has been appointed road foreman of engines of the Erie, with headquarters at Cleveland, Ohio, succeeding J. E. Bleutge, resigned to accept a position as traveling engineer with the American Expeditionary Forces.

A. B. SHANKS, general foreman of the Missouri, Kansas & Texas of Texas at Smithville, Texas, has been appointed master mechanic with the same headquarters, with jurisdiction over the points south of Waco, Texas.

SHOP AN ENGINEHOUSE

J. E. BROGDEN, master mechanic of the Atlantic Coast Line at Waycross, Ga., has been appointed superintendent of shops at Waycross, succeeding D. M. Pearsall, whose appointment as superintendent of motive power has already been noted in these columns.

J. E. BURKE has been appointed roundhouse foreman of the Kansas City Southern at Pittsburg, Kans. He was formerly roundhouse foreman of the Chicago & Alton at Bloomington, Ill., resigning from that position in March, 1919.

W. J. SKELTON, roundhouse foreman of the Missouri, Kansas & Texas at Denison, Texas, has been appointed general foreman there, succeeding B. C. Nicholson.

OBITUARY

WILLIAM T. GORRELL, formerly master car builder of the Philadelphia & Reading at Reading, Pa., died December 13, 1919, at his home in Reading. Mr. Gorrell was born near Aberdeen, Md., on January 23, 1844. He was taught cabinet making by his father and then entered railroad work as a car builder in 1869 on the Central Ohio at Bellair, Ohio, later working at his trade on the Cleveland & Pittsburgh at Wellsville, Ohio, and the Pittsburgh, Cincinnati, Chicago & St. Louis at Dennison, Ohio. On April 15, 1873, he began work with the Philadelphia & Reading at the Reading car shop and was successively foreman of the passenger car department, general foreman and assistant master car builder, and on March 1, 1897, was appointed master car builder, which position he held until he was retired and pensioned when he reached the age of 70, on February 1, 1914.

SUPPLY TRADE NOTES

The Streator Car Company, Streator, Ill., is building a new plant at Kankakee, Ill., which will be devoted to the building of steel cars.

The Railway Motor Car Company, Hammond, Ind., contemplates the erection of a power plant and machine shop at its plant to cost approximately \$200,000.

Arthur Haller, of the New York office of the American Locomotive Company, has been promoted into the company's sales department, with headquarters at Chicago.

The Union Tank Car Company announces that it has acquired 120 acres of land in Lima, Ohio, with the intention of erecting car shops in the future on the site.

Willis E. Martin, treasurer of the H. K. Porter Company, Pittsburgh, Pa., died on January 12, after a prolonged illness. Mr. Martin had been connected with this company for 44 years.

H. P. Wingert has resigned his position as general purchasing agent of the American Brake Shoe & Foundry Company to become the president of the American Commodities

H. P. Wingert

Company with offices at 30 Church street, New York. This company is engaged in the handling of fuel and foundry supplies and railway materials. Mr. Wingert is well known in railway circles. Beginning his business life as a messenger boy, he became a telegraph operator and later held positions of responsibility with the Pennsylvania Railroad, the New York Central and the Central Railroad of New Jersey. He resigned as assistant to the purchasing agent of

the Central Railroad of New Jersey to become purchasing agent of the American Brake Shoe & Foundry Company at the time of its organization.

The Air Brake Safety Appliance Company has been incorporated at Indianapolis, Ind., with a capital of \$10,000 for the manufacture of a safety device to be used in connection with air brakes.

A. H. Hawkinson, assistant manager of the Garratt-Calahan Company, has been appointed sales manager with jurisdiction over the railroad and industrial departments, succeeding E. V. Sackett.

C. M. Rogers has resigned as supervisor of stationary plants on the Chicago, Rock Island & Pacific, with office at Chicago, to become manager of service of the Locomotive Fire Box Company, Chicago, with headquarters at 630 Marquette building.

C. C. Humberstone has been appointed Chicago sales manager of the Anchor Packing Company, Philadelphia, Pa., under the jurisdiction of J. T. Landreth, western sales manager, with headquarters at Chicago. Mr. Humberstone was formerly with the engineering department of the Pennsylvania.

The Duff Jack Sales Company, Ltd., located at 245 Oxford street, London, England, has been formed to represent the Duff Manufacturing Company of Pittsburgh in the British Isles, and has been given the exclusive agency in this territory for Duff and Barrett jacks.

The Chicago Flexible Shaft Company, Chicago, has opened a New York office at 350 Broadway, for the distribution and sale of furnaces, forges and heat treating equipment. The office will be in charge of J. W. Lazear, formerly with the Brown Instrument Company, Chicago.

I. F. Baker, of the Westinghouse Electric International Company, who has been located in the New York office of that company for the past two years, is now on his way to Tokio, Japan, where he will act as a special representative of the Westinghouse International Company.

A. S. Winter has resigned as advertising manager of the William Powell Company, Cincinnati, Ohio, to become connected with the sales force of the Fairbanks Company, New York, and will represent this company in Southern Ohio territory. Mr. Winter will have his headquarters at the Pittsburgh office of the company.

A. R. Horn, who served for over ten years as inspector of devices of the Q & C Company, New York, in connection with its Chicago office, died at Minneapolis, Minn., on December 28, 1919, at the age of 70. Before his connection with the Q & C Company Mr. Horn was division superintendent of the Wisconsin Central Railroad.

Evarts S. Barnum of the G. M. Basford Company, New York, died at his home in Ridgewood, N. J., on February 3, of pneumonia, after an illness of eight days. Mr. Barnum was born in Louisville, Ky., in 1883 and received his education at Purdue University, from which he graduated in 1906. His entire business life was connected with railroad work. Immediately upon his graduation from the University, he entered the service of the Pennsylvania Lines West as apprentice and worked successively as apprentice, machinist, foreman, general foreman, roundhouse foreman and motive power inspector. Leaving the railroad in 1917 he joined the editorial staff of the Simmons-Boardman Publishing Company as an associate editor of the *Railway Age* and the *Railway Mechanical Engineer* and later became associated with the G. M. Basford Company and was in charge of the copy department of that company.

E. S. Barnum

The Wm. Graver Tank Works, Chicago, announces that it has changed its name to the Graver Corporation. There is no change in the management, ownership or directorate.

C. H. Beck, special representative of the Safety Car Devices Company at Pittsburgh, Pa., succeeds C. R. Ellicott as assistant eastern manager at New York.

Errett V. Sackett, who has been manager of the railroad department of the Garratt-Callahan Company for the past five years, has resigned to accept a position as assistant to the president of the Seller Distributing Company, Detroit, Mich., taking charge of sales. This company is the foreign

distributor for a large number of American companies. Mr. Sackett left for Europe early in January to study conditions in England and the Continent, to return about May 1.

C. P. Patrick, vice-president of the Master Boiler Makers' Association, and general boiler inspector on the Erie, has been appointed general manager of the Chicago Wilson Welding & Repair Company, with headquarters at Chicago, succeeding E. S. Fitzsimmons, who has resigned to become assistant sales manager of the Flannery Bolt Company, Pittsburgh, Pa.

Arthur A. Frank, in charge of the western territory of the Standard Railway Equipment Company, New Kensington, Pa., with office at Chicago, has been elected president of the company. Mr. Frank was born at St. Louis, Mo. For a number of years he was connected with the transportation and mechanical departments of the Missouri Pacific. In 1911 he entered the supply trade field as secretary to the president of the T. H. Murphy Company, New Kensington, Pa., and later was promoted to the position of factory manager. In 1914 he was appointed sales agent of the Standard Railway Equipment Company in charge of the southwestern territory, with office in St. Louis, Mo. In July, 1918, he was transferred to Chicago, in charge of the entire western territory, which position he retained until his recent election as president. In addition to the presidency of the Standard Railway Equipment Company he will retain his office as vice-president of the Pressed Steel Manufacturing Company, the Imperial Appliance Company and the Union Metal Products Company.

A. A. Frank

The Cleveland office of B. M. Jones & Co., Inc., New York, selling agents for Mushet steels and Taylor iron, has been moved from 824 Engineers building to 115 St. Clair avenue, N. W., where the office and warehouse have been combined. Walter E. Sargent, formerly of Detroit, Mich., is now connected with the New York sales office of the company at 192 Chambers street.

The Locomotive Export Association of New York City has filed papers with the Federal Trade Commission in accordance with the provisions of the Webb-Pomerene Act setting forth the details regarding its organization to export locomotives and parts thereof. The stockholders include the Baldwin Locomotive Works, the American Locomotive Company and the Montreal Locomotive Works.

The Vanadium Corporation of America, 120 Broadway, New York, has bought all of the properties, excepting cash, receivables and securities, of the Primos Chemical Company, the Primos Exploration Company, and the Primos Mining & Milling Company, producers of vanadium, molybdenum, tungsten and other steel alloys, and having valuable deposits of these elements in Colorado, and a large refining plant at Primos, near Philadelphia, Pa.

The Norton Company, Worcester, Mass., has under construction a new plant at Hamilton, Ont., for the complete manufacture of Norton wheels. The manager of the new plant is R. C. Douglas, formerly a representative of the com-

pany in upper New York state and Ontario. Mr. Douglas will be assisted in his work of organization by several foremen from the Worcester plant. It is expected that the Hamilton plant will be completed, ready for operation, by April or May.

Arthur E. Blackwood, manager of the New York office of the Sullivan Machinery Company, Chicago, has been promoted to vice-president in charge of finance and accounting, with headquarters at Chicago. Louis R. Chadwick, manager of the company's office at Spokane, Wash., has been transferred to the New York office, succeeding Mr. Blackwood. Robert T. Banks, sales engineer, with office at El Paso, Tex., has been promoted to manager of the Spokane office, succeeding Mr. Chadwick.

Joseph Robinson, the inventor of the Robinson connector and formerly president of the Robinson Connector Company, has again become associated with the company. This follows an absence from the company of two years during which time Mr. Robinson has had no managerial or mechanical association with it. In his new association he will act in an advisory capacity, working in co-operation with A. R. Whaley, vice-president of the company and formerly vice-president of the New York, New Haven & Hartford Railroad. Mr. Robinson was born in Dayton, Wash., on July 21, 1889. His family later went east to Illinois where, after leaving school at the age of 12, he worked on a farm until he was 14. He then went west again and worked in a blacksmith shop until the age of 18 when he opened an office at Salem, Ore., as a designer of special machinery. While doing this work his attention was drawn to the need of a better means of coupling hose on railway trains. He worked out the design of the Robinson connector for this purpose and after a study of the problem he came east with the device in 1909 and in 1910 organized the Robinson Connector Company of which he became president. For the next eight years he devoted his efforts to the development of the business represented by the company, until 1918, when he turned his interest over to other hands who, since that time, have been developing the device, Mr. Robinson retaining only the ownership of the patents, but no other connection than lessor with the company, until his return to it as noted above.

Jos. Robinson

The Conradson Machine Tool Company, Green Bay, Wis., has been incorporated recently with C. M. Conradson, at one time associated with the Gisholt Machine Company and later engaged in general consulting work in tool design, as president. The products of the new concern, consisting of milling machines, lathes, planers and radial drills will be marketed by Joseph T. Ryerson & Son. Work was begun on the Conradson plant in the spring of 1918 and was completed recently. Equipment is installed and production now under way.

The Kearney & Trecker Company, Milwaukee, Wis., announces that since February 1, 1920, the Cleveland, Ohio, office and warehouse of the company has been located at 738 Superior avenue, N. W., where larger quarters are occupied and where a line of Milwaukee milling machines,

attachments and accessories will be carried. C. J. Sturgeon, formerly with the W. M. Pattison Supply Company, Cleveland, will be in charge of sales in the Ohio territory, succeeding C. C. Bauschke, who has resigned to engage in business on his own account.

The Westinghouse Air Brake Company, Pittsburgh, Pa., has created an export department to provide facilities adequate to handle the increasing export business and to develop its foreign trade to a greater extent than has been heretofore possible, with headquarters in the Westinghouse building, Pittsburgh, Pa. E. A. Craig, who has been appointed manager of the export department, has been associated with the Westinghouse Air Brake Company for 32 years. The new department will be represented in the New York office by W. G. Kaylor, and in South America by R. M. Oates.

Lester W. Collins has been appointed chief engineer of the Refrigerator Heater & Ventilator Car Company, with offices in the Merchants National Bank building, St. Paul, Minn. During the war emergency, Mr. Collins was connected with the United States Department of Agriculture as refrigeration technologist in charge of the development of a standard heater car for the protection of perishable lading in transit, for the refrigerator car committee appointed by the United States Railroad Administration. For seven years previous to his government service, he was an assistant to H. B. MacFarland, engineer of tests of the Santa Fe, and he was in charge of the special transcontinental tests made for the Santa Fe Refrigerator Despatch Company, on California fruits and vegetables handled in this company's equipment.

Kingman Brewster, until recently associated with the Greenfield Tap & Die Corporation, has been appointed president of the Millers Falls Company, Millers Falls, Mass.

Kingman Brewster

Born in Worthington, Mass., in 1882, Mr. Brewster was educated in the public schools of that town, Williston Seminary, Amherst College and Harvard Law School. He graduated from the latter in 1911 and in the same year was admitted to the bar in Oregon, practicing law there until 1914. He returned east to practice law in Massachusetts and in 1917 served as registrar and counsel of the Federal Land Bank of the First District; also counsel for the Besse System stores and other corporations. In 1918 Mr. Brewster became vice-president and general sales manager of the Greenfield Tap & Die Corporation. Mr. Brewster has recently been appointed to his new position as president of the Millers Falls Company.

The Falls Hollow Staybolt Company, Cuyahoga Falls Ohio, announces the appointment of the following sales representatives: Charles Hubbard & Co., 81 Fulton street, New York; Warren Corning & Co., Transportation building, Chicago; Certes Supply Company, Frisco building, St. Louis, Mo.; Spalding & Small, 1010 Hurt building, Atlanta, Ga.; Read-Rittenhouse Company, 1234 Commercial Trust building, Philadelphia, Pa.; Berger-Carter Company, Tenth and Mississippi streets, San Francisco, Cal.; A. M. Castle & Co. of Washington, Seattle, Wash.; and Austin & Doten, 102 North street, Boston, Mass.

The Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa., has announced the following promotions among its officers at East Pittsburgh: Alexander Taylor, for many years manager of works, has been made assistant to vice-president in general charge in all plants of production, stocks and stores. R. L. Wilson, general superintendent, has been promoted to works manager of the East Pittsburgh works. E. R. Norris has been appointed director of works equipment in charge of machinery, tools and methods in the various plants. Other appointments include: G. M. Eaton, chief mechanical engineer of the company; C. W. Johnson and H. W. Cope, assistant directors of engineering; C. H. Champlain and E. S. McClelland, assistant works managers; F. E. Wynne, manager of the railway equipment engineering department; and G. H. Garcelon, manager of the small motor engineering department.

A. N. Lucas, superintendent of the locomotive shop of the Chicago, Milwaukee & St. Paul, at Milwaukee, Wis., left the service of the railroad February 1 to become district manager of the Oxweld Railroad Service Company, with headquarters at Chicago. Mr. Lucas was educated in the public schools of Green Bay, Wis., and entered railway service at that point as a boilermaker apprentice. Late in 1881 he went to the Chicago & North Western shops at Escanaba, Mich. He remained there until January, 1883, and then returned to Green Bay, Wis., to enter the service of the Milwaukee Northern, now part of the Chicago, Milwaukee & St. Paul System. Here he was subsequently appointed boilermaker foreman. In January, 1901, he was transferred to Dubuque, Iowa, in charge of the boiler shop, remaining there until April, 1904, when he was transferred to the Milwaukee shops. Soon after this he was advanced to the position of general foreman of boiler work for the entire system. In May, 1917, he was promoted to the position of assistant superintendent motive power and a year later was placed in charge of the locomotive department of the Milwaukee shops as shop superintendent. Mr. Lucas is a past president of the Master Boilermakers' Association and is at the present time a member of the executive board of that organization.

A. N. Lucas

The Barco Manufacturing Company, Chicago, has increased its capital stock to \$500,000 and contemplates building a new factory to accommodate the manufacture of several new devices which it expects to put on the market in the near future.

The Pollak Steel Company, Cincinnati, Ohio, manufacturers of railroad car axles, locomotive forgings and heavy forgings for marine and machine builders, with plants at Cincinnati and South Chicago, Ill., announces that it has recently added to its South Chicago plant a large extension for the manufacture of drop forgings for the automobile, tractor and agricultural implement trade and has added to its Cincinnati plant a large extension for the manufacture of automobile parts. The Pollak Steel Company has also just closed negotiations with the Interstate Iron & Steel Company, Chicago, for the purchase of its rolling mill property at Marion, Ohio. In addition to its manufacture of specialties, such as automobile parts and drop forgings, which

cannot be measured on a tonnage basis, this now gives the Pollak company a capacity of both forged and rolled products of approximately 300,000 tons a year.

S. F. Bowser & Company, Inc., have extensive plans under consideration for expansion during the present year. The company plans the erection of a warehouse and office building at Dallas, Tex., and the organization of a subsidiary corporation to be known as S. F. Bowser & Company of Texas, for the sale of the Bowser products throughout that state and adjacent territory. E. P. Murray, formerly assistant general sales manager, with headquarters at Chicago, will assume the management of the new company at Dallas. During the war the company closed its branch offices at Denver, Colo., Memphis, Tenn., and St. Louis, Mo. These offices will be re-established, A. S. Bowser, assistant to the treasurer, with headquarters at Fort Wayne, Ind., having been appointed manager of the Denver office; B. L. Prince, who has been district manager of the Dallas office, has been transferred to the Memphis office, and Willard D. Smith, connected with the sales department, has been appointed manager of the St. Louis office. A new district office will be established at Detroit, Mich., and L. E. Porter, assistant district manager at Fort Wayne, Ind., has been appointed district manager of the new Detroit office.

National Steel Car Company Changes Hands

Robert J. Magor and associates have bought the plant and property, and taken over the assets and liabilities of the National Steel Car Company, of Hamilton, Canada, and will continue the business under the name of the National Steel Car Corporation. The plans of the new corporation are to substantially increase its freight car manufacturing facilities and also develop on a large scale the motor truck business, which in the old company was only carried on in a very small way.

Mr. Magor, who is president of the Magor Car Corporation, New York, engaged in the car building business, has been elected president also of the new corporation. He was born on July 6, 1882, at Montreal, Canada, was educated in high schools and also received private tuition. In November, 1905, he entered the car building business with the Canadian Car & Foundry Company and in June, 1910, left the service of that company to take over the management of the re-organized Magor Car Company plant at Passaic, N. J. Since Mr. Magor took over the management of this plant the production has been increased ten times, and extensions are now being made, to be completed in the early spring, that will double the present capacity of the plant. In 1912 Mr. Magor assisted in designing the plant of the National Steel Car Company, Hamilton, Canada, and two years later was elected to the board. In the early part of 1919 he was made consulting vice-president, and as the company sustained large losses on a French war contract it was necessary to reorganize it, additional capital being put in. This was done by submitting to the company a proposition of purchase, which was accepted, and on December 18, 1919, the purchase was completed and Mr. Magor elected president of the National Steel Car Corporation, Ltd.

R. J. Magor

Railway Mechanical Engineer

VOLUME 94, NUMBER 3

New York—MARCH, 1920—Chicago

ESTABLISHED IN 1832

Published Monthly by Simmons-Boardman Publishing Co., Woolworth Building, New York, N. Y. Subscription price, United States, Canada and Mexico, \$2.00 a year; foreign countries, \$3.00 a year. Entered as second-class matter, January 27, 1916, at the post office at New York, N. Y., under the Act of March 3, 1879.

From the time of Tubal Cain—
The Quality of a product has depended principally upon the standards set up and held to by its makers.

"Red Cut Superior"

The Nationally known—First Quality
HIGH SPEED STEEL

contains the highest grade raw materials, which before being used are subjected to exhaustive scrutiny by our metallurgists. Every bar of the finished product is a composite expression of skilled *Tool Steel* makers to whom *from father to son through many generations*, the word Quality has been a living ideal.

Red Cut Superior The Best for All Machine Work.

Pouring High Speed Steel Ingots

After the liquid steel has been poured off, the ladle is lifted by a crane to its position on one of our large, powerfully built carriages. These carriages travel, at the will of the operator, the entire lengths of ingot molds, filling, from a bottom opening, each ingot mold rapidly and without loss of metal. Central Pouring is thus assured.

"Consistently Uniform" is our motto—and it is absolutely and invariably maintained.

Among the defects which, like hot boxes, seem to recur at more or less regular intervals, one of the most troublesome

Lubrication of Cylinders

is repeated failures of cylinder packing. When such an epidemic occurs the blame is usually placed on the material from which the rings are made, the lubricating oil, or the condition of the feedwater, but very often it is necessary to make some changes in the design of the locomotive before the trouble is overcome. It is generally admitted that more difficulty is experienced in lubricating the cylinders of superheated locomotives, yet the quality of the oil apparently is not as important as the method of operating the engine. By keeping air and front end gases out of the cylinders, oil with a low flash point can be used with good success. Vacuum relief valves have not met with favor on superheated locomotives and many roads consider even by-pass valves unnecessary.

The manner of application of the lubricant is a matter on which there is considerable difference of opinion. On some roads the oil is fed to the valves only; on other roads pipes are run to both the valves and the cylinders, while some lubricate the cylinders only. It is worthy of note that some remarkably good cylinder packing mileage records have been made on roads that have adopted the practice of lubricating only the cylinders. It is found that the exhaust steam carries enough oil to the valve cages to lubricate them properly and the small supply thus secured prevents heavy deposits of carbon around the rings. There is also a growing tendency to dispense with swabs on the piston rods. If the cylinder is properly lubricated the rod itself will carry enough oil to lubricate the rod packing. One road that had adopted cylinder lubrication without swabs averaged 65,000 miles per set of piston rod packing on superheated locomotives.

The higher cylinder temperatures obtaining with superheated steam have brought about marked changes in the

design of piston packing rings. Wide rings have been found unsuited for this class of service and many roads have secured excellent service from rings having a width of $\frac{3}{8}$ in. Gray iron does not possess sufficient strength for such narrow rings and special hard cast iron must be used. With the possibility of further increases in steam temperatures it may be necessary to make other modifications in the arrangement of the cylinders. The bronze faced piston offers another expedient for overcoming difficulties met in lubricating cylinders, but the fact that hard cast iron bull rings and cylinder bushings have been used successfully at extremely high temperatures indicates that it will hardly be necessary to have recourse to such construction.

The past decade has witnessed the substitution of steel castings for forgings in many locomotive and car parts. However, forgings are still used to a considerable extent for parts which are of

The Possibilities of Electric Steel

such shape that they cannot readily be made on a forging machine or power hammer and could be made more cheaply if cast. While the field for ordinary steel castings has no doubt been practically exhausted, the possibility for wider application of electric steel castings in place of difficult forgings deserves thorough consideration. The casting of steel by the electric furnace process allows of more accurate control of the chemical composition and gives the product a higher tensile strength than can be secured by the open hearth process. While the cost is higher than that of ordinary steel castings, it would not be as great as the expense of making even a fairly simple forging.

By making some parts that are difficult to forge, such as safety chains for locomotives and cars, of electric steel, a marked saving should result and the strength might also be

considerably increased. For example, the specifications for electric cast steel chain specify an ultimate strength more than 40 per cent higher than for the corresponding size of welded iron or steel chain. Aside from the substitution of electric steel castings for forgings there should be a wide field for the use of this material in parts that are subject to failure. Often some cast parts of locomotives or cars do not possess sufficient strength and cannot readily be redesigned. The use of electric steel should overcome the difficulty, because it reduces the failures in sections that are difficult to cast and gives the parts both higher elastic limit and greater ultimate strength.

Not infrequently a valve setter will connect up the motion work of a locomotive and roll the wheels, only to discover that the valve chamber bushings are a little too near together or perhaps too far apart. This necessitates removing the main valve to adjust or renew the bushings, resulting in a delay in turning the locomotive out of the shop which could have been avoided by careful inspection when the main valves were first removed. The distance from the link trunnion center to the steam edge of the back port of a locomotive with a Walschaert valve gear is very important; at least it should be the same on both sides, or the valve setter will be obliged to make corresponding alterations in the right and left valve stem lengths. If the check is made soon after removing the motion work from a locomotive there is ample time to make necessary alterations without delaying the valve setter later on. The article referred to on page 166 describes a gage for measuring this distance and also indicates a method of handling motion work and valve gear parts through the repair shop that has speeded up the work and made possible not only a greater output but a better operating valve gear.

Expressed in its simplest terms, the idea has been to get busy with the repair work just as soon as the locomotive was stripped, carefully checking all fundamental valve gear dimensions, making all valve gear parts correspond with the blue print, and getting those parts back to the erecting shop promptly. With this method locomotives are not delayed by mistakes found at the last minute. The valve gear parts, being all standard, go together quickly and easily. No extensive alterations are needed and the work of the valve setter is greatly facilitated.

With the increased weight of locomotives it has been necessary to provide heavier driving boxes and much larger bearing surfaces between the driving box shoes and wedges and the frame jaws. It is not uncommon today to find frame jaws 6 or 6½ in. wide and 26 in. long. These jaws must be maintained both square and true. Every time the driving wheels revolve a pressure of 80,000 lb., or even more, is transmitted through the rods and wheels to the frame jaws. A variation of 1/64 in. is often sufficient to cause shoe breakage. Any one who has ever taken a file and attempted to straighten one of these large frame jaws will admit that it is both a long and tiresome job. The frames are composed of tough steel, which it is almost impossible to remove in any considerable amount with a file, and if the frame is worn out of true as much as 1/16 in., it is necessary to use a hammer and chisel to chip the bearing. This again is a time consuming operation.

It is absolutely essential that frame jaws should be maintained straight and it seems probable that a considerable saving could be effected by the use of a portable milling machine or grinder to do the work. Several successful port-

able machines of this type have been devised but have not been adopted to any considerable extent up to the present time. While the portable milling machines are reported to have given good satisfaction, it seems probable that the best results could be obtained by the use of a grinding machine. After a locomotive has been in service for eight or ten months without having its shoes and wedges renewed, a careful inspection of the frame jaws will usually show that they are worn slightly out of true and the bearing surface is hardened and glazed. In fact, the bearing surface of the frame jaw has the appearance of being almost casehardened. The hardened surface is very difficult to remove with a file and a milling cutter would have to take a cut sufficiently deep to get under it. This difficulty would be obviated by the use of a suitable grinding machine. Such machines have been developed and it is probable that they will be extensively used in the future.

There has been much criticism of the shopmen's wage schedule, which was made effective by the Railroad Administration, because it does not provide for continuing special apprenticeship courses for college graduates in railroad shops. Some of the university authorities have even gone so far as to protest against this to the mechanical department of the Railroad Administration. One of our correspondents took up the cudgels in favor of the college man in a letter which was published in the *Railway Mechanical Engineer* of January, 1920, page 4.

College Men and Railroad Work

Why should the college graduate be granted special favors? It is true that the railroads need him—and need him badly—but why discourage those who have not had this special training by practically serving notice on them that the college man, by being given special training, will be rushed into the more desirable official positions? On another page we publish data as to the number of apprentices in each craft on all of the roads under federal control. If the railroads will awaken to their full responsibility (and they have fallen far short of it) in the matter of recruiting and training their employees, the question of the college man in railroad service will automatically solve itself. Would it not be far better, for instance, to give those of the regular apprentices who show marked ability along certain lines an opportunity to take up a technical course or of adding to their technical knowledge beyond that which is taught in the ordinary apprentice courses on a road which has a modern up-to-date course of training? George M. Basford as far back as 1905 made the statement that “the special training of young men from without the ranks of the workers, for official positions, is fundamentally wrong, and furthermore it plays strongly into the hands of those who wish to see men levelled into classes and considered as on uniform levels as to the value of service.” The railroads need technically trained men—lots of them—but why not go at the task of recruiting them in an intelligent, orderly and logical fashion?

Railroads will continue to take college men into their organizations from outside; but these men need not be given special privileges. Let them come into the organization on their ability and merits, and let them demonstrate their fitness for official positions in competition with others who may have less technical training. Do not further handicap the ambitious young man in the ranks, but rather get behind him and help him to overcome the handicap he already carries. Do not lose sight also of the fact that the successful executive must understand and appreciate the importance of the human factor; the man developed from inside the organization who has had to rub shoulders with the workmen in the formative period of his life may have advantages in understanding his

fellows, which if properly appreciated will give him a big advantage, if his technical training is continued, over the college man who comes into the organization for the first time after he has completed his technical training.

It may not be amiss in this connection to quote the following paragraph which is part of the conclusion of Mr. Basford's address to the 1905 convention of the Master Mechanics' Association: "For the men and officials of the future, technical education is required, but it must be obtained while the student otherwise prepares himself for his work. It must go hand in hand with his education in the service, and the education must be arranged especially to suit his needs. For the engineering education he must not be required to fit himself to existing schools. A new school must be developed specially for him. Instead of giving years to subjects which are merely good for mental training, he must give months to those which he will remember. Moreover, he must not separate himself from active work and responsibility for long periods in order to attend school."

Elsewhere in this issue there is published a communication which calls attention to pending legislation making the use of the metric system compulsory. The author of the letter sums up the objections to the introduction of this system from the standpoint of the mechanical department and his arguments against

**Compulsory
Metric
Legislation**

its adoption should be carefully considered, as the issue is one which must be met squarely when the bill is introduced before Congress. Similar proposals for requiring the use of the metric system have been made before and have been rejected. Nevertheless, it is a mistake to assume that this measure will fail and that active opposition is not necessary. The present agitation for the metric system is due to the organized propaganda for the World Trade Club. It is sponsored by an individual who has made the metric system his hobby and has furnished large amounts of money to carry on the campaign, which has been so conducted as to make it appear that there is an overwhelming sentiment in this country for the adoption of the metric units. Unless industry in general makes known its opposition to the proposed legislation, there is danger that an active minority will be able to secure the enactment of legislation that will be burdensome and detrimental to the business of this country.

The metric system has had every opportunity to displace the present system in the United States. If its merits were as great as the advocates of this system claim, compulsory legislation should not be necessary to secure its adoption. Metric weights and measures have been used in France since 1793, and although penalties have been imposed for the use of the system formerly in vogue, the old units are in use even today in some of the French industries. The metric system has been legal in the United States for many years, but the advantages which it possesses have not proved sufficient to lead to the displacement of the English units. One prominent company which adopted the metric system when the business was founded abandoned it after 30 years. Other industries have had similar experiences, and at the present time the metric system is used in this country only in scientific work.

The metric system has been in use for a sufficient length of time to demonstrate whatever merits it possesses. The experience of other countries which have made the use of metric units compulsory proves that the old units never entirely disappear, but the metric units are added to those already existing, creating additional complication instead of the simplicity which is claimed for the system. Railroad men should realize the danger of compulsory metric legislation and should not allow laws which would affect them so directly to be passed without having their protest heard.

COMMUNICATIONS

I. A. OBSERVES ROUNDHOUSE OPERATION

WASHINGTON, D. C.

DEAR EDITOR:

While Imperial Government are operate RR, I. C. C. detectors no longer can issue Form 5 invitation on hon. MM, so U.S.R.A. employ Jap detector as Shop detector. It our august duty to learn why former proud haughty RR and MM find impossible to keep running U.S.R.A. std. locomotive and car.

In pursuit of duty, Hon. Boss Detector send for me pos haste. I execute double quick to headquarters and learn Hon. Boss much exercised for Green River Jct.

RR building new roundhouse there, which are not perform right. Jap detector empowered to find what are wrong without delay.

Arrive Green River Jct. Find engines standing emitting steam to atmosphere, which are very cold and result in condensed steam return to earth like snow. Detect further find loco. house situate on bank of river which looks fine, but it are situate so close to bank, that outside wall turn table pit are in river. This account for phenomena observed when RH are approached. Juice have fail on motor, which make it nice to push 90-feet table by hand when river are on one side.

Roundhouse look out west, so when doors open let engine out, let wind in, which result in economy; as do without sweeper.

Find machines all motor push, which are good. However, main transmitter are blow out on occasion visit; no table, no machines, no pump, no water for boiler—whole damn works go to hell fast. But RR demand engines. RH foreman tells them, "engines here, he are impotent, come get 'em."

Detect no sand; reason it are froze. RR order when hot climate, get it when begin to be cold. No men to unload, stand, freeze tight, no sand. Picks, dynamite, sand stick by car like rock of gibraltar. Build fire in car, thaw some, but only one sand-stove to dry sand. RH foreman, swear, say, "take sand to stick by job."

Report back Hon. Boss, Green River Jct. all right, if build right. Advise he send chief shop line-drawer to operate.

INO AMSURA.

EXHAUST NOZZLE AREAS

CHICAGO, ILL.

TO THE EDITOR:

In designing the essential features of a locomotive on the horsepower basis, the boiler pressure and the diameter of the cylinders can be inversely varied without affecting the result. To illustrate the point, the diagram herewith shows two locomotives having the same boiler, but by reason of using different pressures the cylinders have different diameters. The tractive effort, speed and power remain unaffected—the two machines are equal.

The amount of fuel burned and the water evaporated produce a constant volume of products for ejection through the stack, which of course remains unaltered, being designed on the basis of horsepower.

The function of the exhaust jet is to eject through this fixed size of stack a definite bulk and pressure of used material. A logical step is to make the exhaust nozzle size constant. In its course from the boiler to the nozzle tip the steam has been subject to equal losses from expansion, cool-

ing, etc. If it flows out at a constant pressure it performs a constant amount of work in clearing the smoke box, producing combustion. This would normally produce different back pressures in the cylinders, the higher in the smaller cylinder and a lower pressure as the diameter of the cylinder increases.

If now having laid down the prime idea, we admit that modifications should be, or would be introduced in practice, we still have little reason to believe that such a difference as exists under the present method (shown on the sketch—5 3/16 and 5 5/8 in. diameter) would be required to accommodate them.

This is not a proposition to increase nozzle sizes. It

It would rather seem wise to accept the average of the present practice calculated on this new basis as the foundation. The very considerable increase in size found practicable in tests not long since is consistent with this method. Just as reasonably would a reduction in size for other locomotives follow and benefit be expected. Averaging present practice would have:

- 61 hp. per square inch nozzle area for 1,200-hp. boiler.
- 69 1/2 hp. per square inch nozzle area for 2,000-hp. boiler.
- 76 1/2 hp. per square inch nozzle area for 2,800-hp. boiler.
- 79 1/2 hp. per square inch nozzle area for 3,200-hp. boiler.

Thus a starting point could be established. So far as is known no practical systematic test of this plan has been made, but this idea is presented in the belief that it has legitimate interest for builders and users of locomotives.

S. C. FRANK.

COMPULSORY METRIC LEGISLATION

SAN FRANCISCO, Cal.

TO THE EDITOR:

Do the readers of your magazine fully realize the effort being made both in this country and in England to make the use of the metric system (the gram-meter-liter system) of weights and measures compulsory? A live, active organization is behind the movement, and so effectively has it worked that legislation is already pending both in our own National Congress and in the British Parliament which, if enacted into law, will not only make the decimal or metric system standard but will prohibit the use of our present system. From organized headquarters circulars are being sent out by the advocates of this legislation, urging the recipients of this literature to immediately write their Congressmen, the Bureau of Standards, Department of Commerce, President Wilson, Lloyd George and the British Parliament endorsing the proposed legislation, in order (so they claim) "that America and the English-speaking people in general may keep pace with the rest of the world" and our industrial development be no longer hindered by what they term "an antiquated jumble of weights and measures deliberately fastened upon us by Germany." So active have the champions of the metric system been that unless the opponents of the proposed change awaken to the seriousness of the situation there is great

danger of this legislation being passed before those most vitally concerned really know what is going on.

It is not the purpose of this letter to discuss the merits of either system. We are willing to admit even that were we back to the days of creation or even to the beginning of our present industrial development we might favor the decimal system as being slightly superior to the system now in use. But the question of changing at this stage of the game to *any* system, no matter how superior it might be, is a very different proposition and involves such serious consequences that we believe it merits most careful consideration.

It is easy enough for a handful of college professors, or a World Trade Club with no financial interests involved, or possibly with an axe to grind, to advocate the adoption of a world standard system of weights and measures and to try to prevent the use of the system now in use; but before deciding to follow their advice it is well to consider the disastrous effects that would follow any attempt to change from one system to another.

Industry would be demoralized. Every machine for making a bolt or nut, a tap or a die would have to be redesigned. Likewise the machines used in the making of other machines. Every specification for a locomotive or car, an automobile or power plant must be changed. Boilers and cylinders must be redesigned. Pressures in pounds per square inch must be converted to grams per square centimeter. In fact, every device entering into the construction or repair of anything of a mechanical nature must be redesigned to conform to the new standard. It is difficult to conceive which would cause the worst jumble, to make the change instantly or gradually, but it would be a physical impossibility to make such a change instantly. If the change were made gradually, during the period of transition we would be confronted with the encumbrance of two sets of standards, some parts being made by one and possibly its corresponding part by the other system. The theorist may tell you that the actual sizes need not be changed but only the terms used to designate the dimensions, but any mechanic knows the serious consequences that would arise from trying to fit one part designed by one system with another designed according to a different system, having no exact equivalent to any unit in the first system.

Moreover, every drawing, or tracing, or blue print would have to be changed and most of them scrapped. Do you realize how serious this phase alone would be? Text books and reference books and file copies of many magazine articles would become obsolete. What a jumbled mess it would all be!

Workmen would have to be re-educated. Through years of training and experience they have become accustomed to our present system. To discard this and replace it with any other system, even though slightly superior, would greatly impair the efficiency of our shop forces for at least a generation to come. The mechanic must not only be able to use the standard system of measurements, but must be able to *think* in terms of them; otherwise we cannot expect him to greatly further the progress of industrial development.

Surely no arbitrary legislation should be enacted without the full knowledge and consent of those most vitally concerned in our industrial welfare. It is easier to scramble the eggs than to unscramble them, as politicians and railroad men have found out. We are living in an industrial age—an age wherein greater achievements have been made than in all the preceding days of history. But we are just at the beginning. Surely we should not swap horses in midstream, unless this is found to be absolutely necessary. What group of men are more vitally interested or more competent to pass on this question than your readers? What do you think about the proposition?

A CONSERVATIVE.

ADVANTAGES OF STOKER FIRED LOCOMOTIVES*

Stokers a Necessity on Large Modern Power
Slack Coal or Screenings Not Economical Fuel

BY D. F. CRAWFORD
Vice-President, Locomotive Stoker Company

As there are approximately 5,000 mechanically fired locomotives in the United States, it will be of interest to consider three questions: First, what led to the introduction and continued application of locomotive stokers? Second, what has the experience gained during their development and use indicated? Third, what are the questions brought about by their introduction, which must be considered by the railway officers?

My statement to the convention of the Master Mechanics Association in 1913 contains an answer to the first question. "The development of the locomotive stoker on the Pennsylvania Lines was brought about by a desire to get more tons per train over the road. I had observed in the

and will permit more full utilization of the capital invested both in the locomotive and in the permanent way through increases in tonnage and speed.

Stokers Reduce Transportation Costs

The expense of moving freight does not increase in proportion to the weight of the train, and therefore the larger the train the lower the cost per ton mile. Among the items which may be considered as decreasing in cost per ton mile in some proportion to the increase in tons per train are fuel costs, (which amount to 9.85 per cent of the total expenses) crew's wages, equipment, track structure and signal maintenance, as well as certain other fixed and operating charges.

The effect of the introduction of large locomotives on a given division operated to their capacity (which the mechanical stoker makes possible) is shown by the curve in Fig. 1, in which the crew's wages per ton mile are shown in comparison with the revenue tons per train. This indicates the results that may be expected by the use of locomotives of various capacities.

That there is a definite relation between the coal used per ton mile and the revenue tons per train, is clearly shown by the diagram in Fig. 2, which shows the coal used per ton mile for the various weights of train for nineteen railroads in various parts of the United States, this information being obtained from the annual reports of the railroads included. Notwithstanding the wide variation in traffic, operat-

Fig. 1. Relation of Tractive Effort and Tons per Train to Wages per Ton Mile (1914 Rates Applied to Various Classes of Locomotives).

annual reports of many of the railroads, the tons of train hauled per pound of tractive power was decreasing as the engines grew large. I found that locomotives that were 20 per cent larger than other locomotives were hauling the same trains as the smaller ones and were not realizing the full 20 per cent additional tractive power that the locomotives had. The stoker problem to me was one of decreasing operating expenses by increasing the train load for each unit on which we had to pay interest and maintenance charges."

C. D. Young, after consideration of certain locomotive tests, stated: "If we use 6,000 lb. of coal, and this locomotive is capable of burning 10,000 lb. per hour, or say, if a fireman will fire 6,000 lb. per hour, and the locomotive is capable of burning 10,000 lb. with a stoker, it is then possible for you to obtain the maximum of that locomotive with the stoker, whereas you do not come to 60 per cent of the maximum output with the fireman."

These statements made in 1913 are of equal value and importance in 1919, and after all are the fundamental reasons for the existence of the locomotive stoker. While what we regard as large locomotives were in limited use before the advent of the stoker, its development and application has

Fig. 2. Relation Between Tons per Train and Coal per Ton Mile on Typical Roads

ing, grade and equipment conditions and the quality of the fuels used, the fact that increased train loading brings a decrease in fuel per ton mile is substantiated.

It is of course difficult to state in a few words just what the use of locomotives of large capacity has meant to those making use of the transportation facilities of the country, but, by their use the average revenue tons per train in the United States was increased from 176 tons in 1888 to 357 tons in 1907, and 620 tons in 1917.

*From a paper presented before the Railway Club of Pittsburgh.

This increase in the amount of traffic moved by a train unit permitted the results disclosed below:

Year	Revenue tons per train	Receipts per ton mile	Receipts per train mile	Cost of fuel per train mile	Cost of Fuel per Ton Mile		Price of coal per ton
					Actual price	Equated price	
1888.....	176	\$0.01001	\$1.76	\$0.21	\$0.0006	\$0.0006	\$1.14*
1907.....	357	0.00759	2.71	0.43	0.0007	0.0004	2.20†
1917.....	620	0.00728	4.51				

*Information not available.
 †Estimated from the price of coal in various districts as set by the Fuel Administration and is a conservative figure for the average cost to the railways.

Notwithstanding the fact that in 1917 the price of coal is shown as nearly double that in 1907, the cost of coal per ton mile was practically the same, and when the price is equated to that of 1907, the decreased cost per ton mile given shows conclusively that a smaller amount was used.

Heavy Train Loading Increases Track Capacity

Another important reason for the use of locomotives of the capacity made available by mechanical firing is the reduction of the number of units or trains required to handle a given traffic.

About five years ago query was made as to what would have been the effect if the traffic of a given railway system in the year 1912 had been moved in equipment of the capacity that had been used in 1903. Of course, in making the calculations for the reply, some factors had to be assumed; the conclusions at least indicate the propriety of the increase in capacity of both locomotives and cars.

While a larger number of the smaller locomotives and cars would be required, the fact that the number of units or trains needed so increased the traffic density that, to make the movement with the same degree of promptness as existed in the latter year, the cost of providing additional track facilities far outweighed the cost of the additional equipment. As it is only by the use of a mechanical stoker that the possibilities of large locomotives may be realized, the information given above becomes the reason not only for their development but for their more general application.

Stokers Eliminate Necessity for Two Firemen on Large Engines

In 1903, with locomotives of about 40,000 lb. tractive force and 50 sq. ft. of grate area, from time to time complaints were received from the firemen regarding their arduous work, and frequently men left the railroad service, preferring to seek a more congenial occupation. This, of course, embarrassed the service, as at times it was difficult to obtain sufficient men to supply the demands, and I well remember the concern of those responsible on account of the large turn over and its effect on the operations. As the size of the locomotives continued to increase, the difficulties and complaints grew apace, and it may be said that the climax occurred in 1912, when the firemen in the Eastern Wage Application demanded two firemen on locomotives weighing over 200,000 lb. on the driving wheels.

During the period mentioned, several types of mechanical stokers had been built and put in service, but were regarded by both the railway officers and employees as rather more than less in the experimental stage. Nevertheless such was the confidence of some railway officers in the stoker that what may be regarded as the first commercial application of the device was made in 1910. Since that time the number applied per year has gradually increased to the total of 5,000 in use on the locomotives of at least 71 of the railroads of the United States.

Assuming that 120 lb. of coal per sq. ft. of grate per hour is required to obtain the capacity of the locomotives,

the average coal rate for typical stoker-fired engines would be as follows:

Mikado	Grate 70.5 sq. ft.	Coal per hour 8,460 lb.
Santa Fe	Grate 83.0 sq. ft.	Coal per hour 9,960 lb.
Mallets	Grate 89.2 sq. ft.	Coal per hour 10,704 lb.

Evidently some locomotives of these dimensions are worked below the capacity suggested by the builders' formula of 120 lb. of coal per square foot of grate area per hour, or certainly there would be more stokers in use.

Even if half the amounts of coal per hour given above were to be fired by hand for any considerable length of time, it is probable that the limit of endurance of the men, especially during the warm seasons, would be approached and therefore the stoker will afford the required relief and will be accepted as a substitute for the second fireman so frequently requested. In fact, I am inclined to believe that in time the stoker will be preferred, as by the use of the stoker the period elapsing from employment to promotion to engineer will not be increased, which would be the case were a second fireman employed on all locomotives.

Fuel Economy and Stoker Firing

As it is evident that only the furnace efficiency is affected, whether a boiler is fired manually or mechanically, many of the tests of stoker-fired locomotives which have been made, must be disregarded, as the results obtained clearly indicate failure to differentiate between furnace, boiler and engine efficiency.

Indeed, I can only conceive of one reason why under equivalent draft, structural and adjustment conditions a manually fired furnace should show a better performance than a mechanically fired furnace. That is, that firemen might be able to more accurately distribute the fuel, supplying the fresh coal exactly to the points on the grate required, as indicated by the color of the fire, and I can only think of one reason why the mechanically fired furnace should give the better results, namely, it is unnecessary to so frequently open and close the furnace door, permitting a more uniform fire-box temperature to be maintained.

It is probable that in locomotive practice each of these theoretical advantages offsets the other, especially at combustion rates approaching the limits of manual firing, beyond which the mechanical device is superior, due to the fact that accurate distribution can no longer be made.

The equivalent evaporation per pound of coal depends on the amount of coal burned per square foot of grate per hour rather than whether the furnace is fed manually or by a mechanical device. As the stoker is applied for the sole purpose of amplifying the output of the locomotive by causing more coal to give up the power contained therein, it follows that the evaporation rate will decrease in proportion to the combustion rate obtained.

The coal consumed per gross ton mile cannot be considered an accurate measure of the difference between mechanical and manual firing, as not only are the efficiencies of the boiler and engine variable factors, but the resistance of the train as determined by the number and weight of the cars must be given consideration.

The unit ton miles, while sufficient for rough comparisons, should not be depended upon when definite information is required.

Although it is true that the pounds of coal per indicator horsepower hour, also involves the performance of the cylinders, by careful selection of the locomotives, as to similarity in engine conditions, this unit may be regarded as fairly valuable in making comparisons.

The diagram in Fig. 3 shows the results of some tests where the information obtained is compared on the last mentioned basis. It will be noted that for the higher rates of combustion, and consequently lower boiler efficiency, the curves indicate that the coal consumption per indicated horse-

power hour favors the stoker-fired locomotive, also that when superheated steam is used there is a marked difference in favor of the mechanically fired locomotive. In the latter case, however, the excellent results shown were obtained by increasing the diameter of the cylinder equal to about 10 per cent, as it was found that with the stoker this could be done on account of the ample steam supply. Indeed further experiments justified further increasing the diameter of

The tabulation gives the results obtained on some tests made to develop the facts. It will be observed that the difference when the locomotive is doing the same work is 22 per cent.

Did it ever occur to you that there are really very few experienced stoker firemen? Why should you expect the same results from inexperienced stoker firemen that you obtain from experienced hand firemen? When tests with firemen of equal skill handling the stoker and the shovel show that more coal is being used on the mechanically fired locomotives, you may rest assured that you are getting a return for it either in increased tonnage or increased speed.

Steam Jets Increase Boiler Efficiency

Four of the six types of stokers for locomotives now in service use steam jets to project the coal into the fire-box. It has been stated that the introduction of steam into the fire-box for this purpose results in decreased evaporative efficiency. Just what has led to these statements, I am at a loss to understand, as very early in my railroad experience I was informed as to the desirability of wetting the coal to

Fig. 3. Comparison of Coal Used per Indicated Horsepower Hour with Hand and Stoker Firing

the cylinders equal to about 17 per cent, with a proportionate gain in hauling capacity.

A possible increase of 17 per cent in the earnings per train mile is surely sufficient to be attractive to those responsible

for the financial results of railway operations and to justify the application of a device which permits such conditions.

Fuel Economy Depends on the Fireman

How many of us have taken the trouble to ascertain the effect in coal consumption of inexperienced firemen?

the effect of steam jets on the amount of smoke emitted from a locomotive, and of course one of the factors was the effect on fuel economy.

From the results of these tests published in the American Railway Master Mechanics Association, the data shown in the tabulation was obtained. The data is supplemented by

the following statement: "The tabulated results of the efficiency tests with Pennsylvania Gas Coal (Tests Nos. 2500-79 to 2500-87) with and without the jets are plotted. The curves show that a reduction of smoke results in an increased equivalent evaporation, and a corresponding increase in efficiency and economy with or without the brick arch, showing that the steam jet tubes make for improved combustion and economy rather than simply to "whitewash the smoke."

With this evidence before us, I do not think for the present at least we need be concerned as to the deleterious effect of using steam jets for projecting the fuel into the fire-box, for if the use of as much as 1,000 lb. of steam per hour with 2,000 lb. of coal per hour does not result in reduced economy, certainly the introduction of from 300 to 500 lb. of steam per hour into a fire of 5,000 to 7,000 lb. of coal per hour will not adversely affect either the evaporation or the annual balance sheet of the railways using this arrangement.

Slack Coal Not Economical

We all appreciate that one of the arguments for the introduction of the locomotive stoker was the possibility of using the less expensive grade of coal known as screenings or slack coal, and consequently a number of stokers especially adapted for its use were installed.

Of course it was expected that the decreased cost per

Fig. 4. Relation Between Rate of Firing and Stack Loss, Hand Firing

ton would offset the increased consumption, but the practical difficulty not only of supplying the special coal, but the necessity of carrying two kinds of coal at coaling stations, one for hand and one for stoker-fired locomotives, indicated the advantage of a stoker so arranged that it would handle run of mine or even lumps by breaking it to a suitable size on the locomotive.

There is, however, a much more important reason for avoiding the use of screenings or coal of small size than the inconvenience of providing it prepared or crushing it at the coaling stations. That is, the question of quantity of fuel used.

Some comparative tests were recently made on stoker-fired locomotives. On one series of tests, coal which would pass through a two-inch screen was used, and the other series made with coal which would pass through a 6-inch, but

over a 2-inch screen, in the latter case the larger lumps being reduced by the breaker in the stoker conveying mechanism. The advantage obtained in using the larger coal is apparent and amounted to over 15 per cent.

The principal cause, no doubt, of the decreased efficiency of the finer coal is the loss due to the unburned coal being thrown out of the stack. The amount of this loss of course depend upon the rate of firing and the relative fineness of the coal. The diagram in Fig. 4 shows only the relation between the stack losses and the rate of firing.

The stack losses, which run as high as 15 to 20 per cent of the coal fired, have no other relation to the method of firing except that it is the usual practice to fire at higher rates mechanically than manually.

It should be borne in mind that the stoker is a mechanical device; that it will only do what a human being makes it do; that it cannot tolerate neglect. If it is properly inspected, lubricated, maintained and operated, it will add to the earnings of the railroads, the comfort of the employees and banish troubles due to engines not steaming.

DRIVING BOX LINER

BY A. G. JOHNSON
Mechanical Engineer, Duluth & Iron Range

The difficulty of securing a driving box liner that can be cheaply made, easily installed, and that will give efficient service, has given railroad mechanical men considerable trouble. At one time the Duluth & Iron Range used rolled brass liners fitted into the driving boxes. After this method had been used for some time the practice was adopted of grooving the driving box faces and drilling anchor holes, then sending the boxes to the foundry, where they were laid level and moulded clay placed around the groove, the brass being cast in thick enough to leave plenty of stock for finishing. The boxes were then returned to the machine shop and planed down to the required thickness. This method made a good job, but was found to be too expensive due to the high cost of material and the amount of labor required.

Eventually this method was abandoned and on the larger

The Fibre Liner Held in Place by the Brass Plugs

boxes, where there is stock enough, the face of the box is grooved and 3/4-in. holes bored through the face. Fibre liners held in place with brass plugs driven tightly in the 3/4-in. holes solved the problem. The application of these liners is shown in the drawing. The shape of the liner is laid off on the fibre sheet and sawed out on the band saw, so that it requires no extra fitting, making a very cheap job and one that gives more mileage than the brass liner, at about one-third the first cost.

SCIENTIFIC DEVELOPMENT OF THE LOCOMOTIVE*

Means of Securing Higher Efficiency in the Generation, Distribution and the Utilization of the Steam

BY JOHN E. MUHLFELD

PART II

IN relation to boiler feedwater, observations and experiments indicate that any scale porous to water has little effect on boiler economy. However, such scale when dried out or hardened next to the metal by the expulsion of the carbonic acid, as usually occurs when boilers are forced, will not only become an excellent heat insulator and cause a heat loss of about 10 per cent when $\frac{1}{8}$ in. thick, but it exposes the sheets and staybolts to overheating and "mud burning," with resulting leakage and shopping for repairs and cleaning.

In view of the increasing size of locomotive boilers and the high ratings to which they are subjected, the importance of purifying unsuitable water to prevent incrustation, corrosion, leakage and burning, as well as to eliminate delays and cost of cleaning, repairing and extra fuel consumed, cannot be overestimated.

Boiler Feedwater Purifying

When an adequate and suitable supply of boiler feedwater cannot be obtained from the usual sources, then the proper treatment of the available unsuitable water becomes necessary by settling; filtration; chemical treatment in treating plants, supply tanks or tenders; or, in the case of suspended matter and carbonates, by partial purification in a combination open and closed type of exhaust-steam feedwater heater on the locomotive.

While the supplying of suitable natural or treated boiler water to the locomotive tender is the most satisfactory and economical method, in the absence of such the tender treatment or feedwater-purification method will be an improvement over feeding the raw water into the boiler without treatment, or attempting to treat it in the boiler.

Fuel

The principal fuels now used in steam locomotives are the commercial grades of bituminous and anthracite coal and fuel oil.

Regardless of the kind of fuel now used by steam locomotives, more general attention is being given to its proper preparation for the class of service to be performed and the method of firing to be followed, before it is supplied to tenders. However, the factors of kind and size of coal and method of firing must each be carefully considered and coordinated in order to insure the best results.

Combustion

The capacity of the average steam-locomotive boiler is dependent upon the activity, temperature and radiation of combustion, which in turn are usually controlled by the limitations of combustion when fuel is burned on grates, the furnace volume and evaporating surfaces, the length of the boiler flues, tubes and bafflewall arrangement, and the draft, and not so much upon the inability of the evaporating and superheating surfaces to absorb the heat.

The combustion rate generally follows the increase in draft until about 100 lb. of bituminous and about 50 lb. of anthracite coal are burned per square foot of grate area.

After this the additional coal supplied is not effectively consumed due to the difficulty in supplying sufficient air, uniformly distributed, through the grates and fuel bed to oxidize the fixed carbon and volatile matter in process of combustion without a large excess of air such as obtains when forcing takes place, and it becomes necessary to open the fire door so that combustion can be completed by the admission of air above the fuel bed.

The greatest loss in heat is that due to the heat carried off in the stack gases, sparks and cinders, which usually results in a smokebox temperature of from 500 to 750 deg. F. for the best practice. Adding to this the heat losses due to combustible in ash, vapors of combustion, carbon monoxide and otherwise, leaves an average of from 25 to 40 per cent of the heat in the fuel as fired unabsorbed by the boiler and superheater.

Where locomotives are worked at from 25 to 35 per cent cut-off and hand-fired, with a thermal efficiency of about 65 per cent for the combined boiler and superheater, the heat balance will be approximately as shown in the following table.

	Per cent
Heat absorbed by boiler.....	55
Heat absorbed by superheater.....	10
Heat loss in smoke box gases.....	14
Heat loss in cinders.....	8
Heat loss in vapors of combustion.....	4
Heat loss in combustible in ash.....	3
Heat loss in carbon monoxide.....	2
Heat loss in radiation and unaccounted for.....	4
Total.....	100

However, at high rates of boiler capacity and draft, when stoker-fired coal is burned on grates the front-end and stack cinder and spark losses will run as high as from 12 to 25 per cent, the carbon monoxide from 2 to 7 per cent, and the unburned fuel from 10 to 35 per cent. With the best hand firing, when using dry bituminous coal averaging 14,400 B.t.u. and 60 per cent fixed carbon, 32 per cent volatile and 8 per cent ash, the fuel rates in Table 1, will usually obtain.

TABLE 1. CONSUMPTION OF DRY BITUMINOUS COAL BY LOCOMOTIVE WITH THE BEST HAND FIRING

Total indicated horsepower of locomotive	Dry coal per i. hp.-hr.
500.....	2.8
750.....	2.7
1000.....	2.6
1250.....	2.5
1500.....	2.6
1750.....	2.8
2000.....	3.0
2250.....	3.2
2500.....	3.4

As the locomotive firebox, which in the best practice represents only from 7 to 10 per cent of the total boiler evaporating surface, must generate all and absorb from 30 to 40 per cent of the heat energy that is converted into drawbar horsepower, the fuel effectively consumed, not fired, is the measure of work done. Therefore the largest permissible combination of fire box and combustion-chamber volume, heating surface and grate area should be provided and equipped with an arrangement of firebrick baffle walls placed on water-circulating supports in a manner to produce long flame travel, high firebox temperature and the maximum radiant heat for absorption by the surrounding water.

With the usual limitations in firebox volume, too much

*The first section of Mr. Muhlfeld's paper, which was presented at the annual meeting of the American Society of Engineers, appeared in the January issue of the *Railway Mechanical Engineer*.

importance cannot be placed on the arrangement of heat-absorbing and radiating walls for the purpose of flame and radiant-heat propagation. Carefully conducted tests have shown that the best results are obtained from solid firebrick baffle walls and that the unburned-gas, coal-dust, spark, cinder and smoke losses are reduced with an increase in their length and gas-passage arrangement, and a saving of from 10 to 15 per cent in bituminous coal as fired is effected.

The greatest difficulty in controlling combustion occurs at high horsepowers and long cut-offs, where grates are used, and for the best results the air openings should be equal to about 50 per cent and those in the ashpans to about 15 per cent of the total grate area so that firebox temperatures of from 2,000 to 2,500 deg. F. can be obtained and the unburned solid fuel, carbon monoxide and excess air over the fuel bed reduced to the minimum.

Other important factors influencing combustion, as well as evaporation and superheating, that should receive consideration are: ratios of length to diameter of boiler flues and tubes and the spacing between them; distribution of gas area between boiler flues and tubes; the effect of closed superheater dampers on firebox draft when locomotive is not using steam; free passage of gases through front end by elimination of unnecessary baffles, steam pipes and superheater parts; arrangement of exhaust stand and nozzle to change form of exhaust jet and produce greater entrainment of gases and improved co-ordination of exhaust jet and stack.

Boiler Water Circulation

Water is practically a non-conductor of heat but expands when heated above 39 deg. F. and rises due to its relatively lower specific gravity. Unimpeded circulation will therefore increase its ability to take up heat, maintain greater uniformity of temperature throughout the boiler, and decrease the liability of incrustation of heat-absorbing surfaces and of priming.

In designing a boiler it is extremely desirable to secure the most rapid circulation practicable, as with high combustion rates and temperatures and the abnormal state and behavior of the water film in contact with the heating surfaces, the load on the firebox sheets is very intense, the conduction rate averaging from 75,000 to 100,000 B.t.u. per square foot of evaporating surface per hour.

Therefore, in order to avoid resistance to heat transfer, with resultant overheating of metal and reduced efficiency, a relatively high velocity of circulation and at least a rate of 125 ft. per min. in the most sluggish locality is very essential.

The average locomotive boiler, with its combination of cylindrical and box shell, water legs, staybolts and rods, flues, tubes and generally irregular design of water spaces does not present ideal water-circulation possibilities, but the enlarging of contracted spaces, increasing of water-leg, flue and tube clearances, and provision of suitable outlets from choked water pockets will not only reduce the resistance to the "slip" of the steam bubbles through the water, but will enable the accelerated action of the former to increase the velocity of the latter and thereby improve general circulation and heat-transfer results.

Heat Radiation, Convection and Conduction

The transmission of the heat of combustion produced in a locomotive boiler is by means of radiation and convection to the firebox, flue, tube and superheater heating surfaces, by conduction to the water in the boiler and the steam in the superheater, and by convection through the boiler water and the superheater-steam mass. In addition there are the direct radiation losses, which in many instances are considerable.

Heat Radiation. In a locomotive boiler the efficiency of combustion heat transfer through the firebox plates and boiler flues and tubes is from 20 to 25 per cent greater as applying to those heating surfaces directly affected when sub-

jected to the radiant effect of the incandescent combustible and non-combustible particles which have passed through the minimum distance, than the heat-transfer efficiency when convection only is available. For example, when coal is hand or stoker-fired and burned on grates or in retorts the radiant heat is at a minimum and applies only to the heat-absorbing surfaces adjacent to the fire bed while the heat of convection is at a maximum; whereas when the coal is burned in pulverized form in suspension this condition is reversed, as is evidenced by the intense incandescent flame which obtains not only in the furnace and combustion chambers of the firebox proper, but well into the boiler flues and tubes. The locomotive boiler of the future will undoubtedly depend more largely on radiant heat.

With respect to the loss of power through radiation to the atmosphere from all parts of locomotive boilers and machinery that are generators and containers of heat and pressure—to prevent which rather indifferent efforts have as yet been put forth, as the rate at which this loss of heat extends will depend upon the difference between the temperature of the body emitting the heat and the temperature and velocity of the surrounding atmosphere, there is sufficient justification for completely and properly lagging the boiler, firebox, cylinders and heads, steam chests and all other radiating surfaces, as well as for polishing certain machinery parts, in order to reduce the dissipation of heat that now takes place through these parts from the existing steam pressures and superheat.

Heat Convection. In the locomotive boiler convection acts particularly in the transfer and diffusion of the heat in the products of combustion throughout the firebox, flues, tubes and superheater by means of the smokebox draft and in the carrying of the heat through the boiler-water mass by the currents produced by circulation. In the present locomotive boiler by far the greatest proportion of the heat is imparted to the boiler evaporating and superheater surfaces by convection.

To secure the fullest benefit from heat convection the combustion volumes and gas areas must be so co-ordinated as to establish a "velocity pressure" or "frictional" action between the gases and the heat-absorbing plates and tubes in order to increase the rate of heat transmission. Likewise must the boiler circulation be expedited in order to quickly disengage and release the steam bubbles from the water side of the same plates and tubes in the final heat transfer. The possibilities for improving heat transmission by convection in the locomotive boiler with its high water rate, *i. e.*, a boiler horsepower for an average of less than two square feet of total evaporating surface, fully justifies additional study.

Heat Conduction. In the locomotive boiler heat conduction is principally associated with the thermal conductivity of the firebox, flue, tube and superheater materials and with the accumulation of soot and scale on the fire and water or steam sides, respectively. Any increase in the rate of external conductivity, considering the present kinds and thickness of firebox, flue and tube materials as practically fixed, must be through an increase in the rate of flow of the heated gases, and this in turn means the expenditure of a greater amount of energy to pull these gases through the boiler.

However, questions as to the proper gas areas, rate of flow of gases, best sizes of flues and tubes for the maximum rate of heat transfer, and relating to like factors should be carefully analyzed in order that the highest absorptive efficiency may be obtained, not only with the high but also with the low gas temperatures. While there is no difficulty in now obtaining a boiler horsepower from each 1½ to 2 sq. ft. of total evaporating surface, whatever further improvement can be made in this direction will provide just that much more margin of boiler over cylinder horsepower requirements and produce a corresponding gain in efficiency.

Steam Generation

Efficient absorption of heat for the generation of steam in the modern locomotive boiler can be more readily provided for than can suitable feedwater, effective boiler-water circulation, efficient combustion or the maximum pounds of dry saturated steam per hour, which latter is a fundamental requirement.

In present locomotive operation the quality of the steam, *i. e.*, the percentage of vapor in a mixture of vapor and water, is one of the most important and least-referred-to factors in road and laboratory test reports, particularly as the average modern locomotive boiler is notorious for delivering saturated steam to the superheater or to the steam pipes with a high percentage of entrained moisture. This is due largely to the relatively small steam space in the boiler, the close proximity of the water level to the throttle valve and the backlash due to the firebox tube sheet, and also to the fact that the most rapid movement of the steam is next to the throttle valve so that any water coming near it is immediately entrained, due to the high velocity.

Road tests recently conducted on modern Mikado types of locomotives showed an average quality of from 94.7 to 96.3 per cent for the saturated steam as delivered to the superheater, indicating from 5.3 to 4.7 per cent of moisture, which is valueless so far as its power for doing work is concerned but which greatly increases the work to be performed by the superheater by throwing upon it work which should properly be done in the boiler.

The delivery of dry saturated steam from the boiler is an item that has been given but little consideration in steam-locomotive practice, the principal idea having been to produce evaporating capacity and depend upon the superheater to perform auxiliary boiler functions. Many changes can and should be made to improve this condition.

Steam Pressure Increase

One of the greatest and simplest improvements to be made in the steam locomotive can be effected by an increase in the boiler pressure in combination with greater quantity and better quality of saturated-steam production, higher and more uniform superheat, and compounding.

While the loss in steam pressure between the boiler and the valve chests of saturated-steam locomotives is considerable, this loss is substantially increased in a superheated-steam locomotive. Tests have indicated that the loss in boiler pressure at the valve chests when working at low rates of speed and cut-off will be about 5 per cent, at medium rates about 10 per cent, and at high rates about 15 per cent.

During recent years stationary-boiler engineers have not only determined upon their efficiency but have inaugurated the use of relatively high steam pressures, and with the urgent necessity for keeping the cylinders as small in diameter and the reciprocating and revolving parts as light as practicable, there would appear to be no good reason for not now utilizing saturated steam of 350-lb. pressure, which, in combination with 300 deg. F. of superheat, should provide, in addition to the many other advantages, a much greater opportunity for economy in power generation.

Steam Superheating

The use of superheated steam has done more to increase sustained hauling power, reduce fuel and water consumption and increase thermal efficiency than any of the other means and methods that have been generally adopted on the steam locomotive since its introduction, either singly or in combination. Sustained hauling capacity is increased, due to the longer cut-off possible at comparative speeds and fuel and water economy result from the elimination of cylinder condensation, the increase in efficiency being progressive and in proportion to the amount of superheat up to the point at which the exhaust steam begins to show superheat.

With the average superheat now used, from 175 to 250 deg. F., the drawbar pull at a speed of 20 miles per hour is increased about 15 per cent; and at 50 miles per hour about 40 per cent; and, due to the combination of superheat, larger diameter of cylinders and reduced cylinder back pressure, resulting from the use of superheated steam, it is possible to increase train tonnage about 30 per cent at speeds of about 30 miles per hour.

In the best existing steam-locomotive practice the superheat generally increases with the cut-off up to 50 per cent cut off, beyond which there is usually a falling off in the superheat. Furthermore, with short cut-off a fair water rate, *i. e.*, about 19 lb. per i.hp., can be maintained; but if the cut-off at the same speed is increased to over 50 per cent the superheat must be increased to about 300 deg. F. in order to maintain the same water rate, or otherwise, for example, at 67 per cent cut-off, the steam consumption will increase to 21 lb. or more per i.hp. This for the reason that as the amount of superheat is increased the range of temperature in the cylinder during the stroke of the piston is decreased, until with sufficient superheat the changes in temperature cease entirely.

While the increased superheat results in a greater number of B.t.u. being exhausted from the cylinder, any such loss of a marked degree is more than offset by the smaller amount of heat exhausted per stroke, due to the fewer B.t.u. admitted to the cylinder per stroke at a given cut-off.

The use of highly superheated steam results in a saving of about 35 per cent of the total water evaporation per unit of power and in from 10 to 45 per cent saving in fuel, when using steam, depending upon the power output.

Existing fire-tube superheaters produce the maximum superheat only when the locomotive is forced to its boiler capacity, whereas the maximum economy is more desirable when the locomotive is working under average conditions at economical cut-offs and when the superheater should give as nearly as possible a uniform degree of high superheat under all conditions of working, regardless of the boiler evaporation. For example, if the degree of superheat obtainable at speeds of 50 miles per hour with 50 per cent cut-off could be obtained at 25 per cent cut-off, a water rate of considerably less than 15 lb. could be obtained, as compared with existing rates of about 19 lb. Therefore, as the present limitation in the hauling power of the modern superheated-steam locomotive is the capacity of the boiler to produce continuously sufficient dry saturated steam of high pressure and of the superheater to maintain a uniform high degree of superheat, the possibility of improving it by means of average higher boiler pressures and superheat temperatures and better utilization of fuel, steam and waste heat, in combination with radical changes in the design and arrangement of the boiler and superheat equipment and in the saturated- and superheater-steam connections, offers one of the greatest opportunities to increase efficiency and economy. This applies particularly to the larger locomotives, many of which consume more fuel and water and do less work than the small locomotives of the same general design and equipment.

The proposed changes, while applying especially to the production of greater efficiency at economical cut-offs for maximum power and speed, would also improve the maintenance and operation of superheaters, boilers, flues, front ends, valves, cylinders, and exhaust nozzles and provide for the better equalization of a lower draft through the flues and tubes, lower front-end temperatures, less throwing of smoke, sparks and cinders, and lower cylinder back pressure, all of which would reduce loss of power, fuel consumption and wear and tear on machinery.

Some of the particular troubles reflected in both maintenance and operation, due to the existing, generally used boiler and superheater equipment, may be stated as follows:

a Air leaks around outside steam pipes where they pass through the front ends, resulting in steam failures, burning out of front ends, reduction in the size of exhaust nozzles for the purpose of making engines steam, and increased water and fuel consumption. *b* Joints between superheater units and the saturated and superheated chambers of the headers leaking, and the cutting out of the units at the neck, between the ball joint and the tube. *c* Too little water and steam space over top of firebox and combustion-chamber sheets and flues, particularly on grades and curves, contributing to lower superheat temperature and cylinder efficiency, and to superheater-unit tubes distorting due to entrained water being carried over with the saturated steam from the boiler to the superheater, causing obstructions in and damage to superheater tubes and obstructions at the header. *d* Extreme losses in steam pressure between boiler and steam chests. *e* Boiler flues clogging, due to ash and cinders packing in around return bends and centering clamps and tubes.

Some of the points to be considered in correcting existing deficiencies may be stated as follows:

Steam Temperatures. The steam temperature should be uniform for the variable speeds and capacities of operation. At the present time high temperatures obtain only at high speeds and capacities. A minimum temperature of 650 deg. F. quickly after starting, and of 700 deg. at maximum power and speed, would be much more effective and economical. For example, a locomotive equipped for generating 350 lb. steam pressure and 300 deg. superheat, representing a total temperature of about 736.4 deg. F., will, as compared with one using 200 lb. steam pressure and 300 deg. superheat—representing a total temperature of about 687.9 deg. F., require an increase of only 18 B. t.u., or 1.3 per cent in total heat in the steam, and an increase of only 48.5 deg., or 7.05 per cent in the temperature of the steam to produce an increase of 150 lb., or 75 per cent in the steam pressure.

Dome or Steam Outlet. This should be fitted with baffles for the purpose of reducing liability of priming and entrainment of water with saturated steam.

Saturated-Steam Delivery Pipe. This should be located outside of the boiler and be of adequate cross-sectional area to reduce steam-pressure losses.

Steam Trap or Separator. A steam trap or separator should be installed between the saturated-steam delivery pipe and the superheated saturated-steam chamber for the purpose of further eliminating moisture and condensation from the superheated units and also as a re-evaporation chamber.

Superheater Header or Saturated- and Superheated-Steam Chambers should be removed from the interior of the front end.

Superheater Units should consist of not more than two tubes per boiler flue and should be of such design and arrangement as will admit of location close to the top of the flue, in order to permit free passage for cinder and ash and cleaning of flues.

Unit Joints to Saturated- and Superheated-Steam Chambers. Unit joints should be removed from the direct path of gases and cinders so as to avoid cutting out, and should be supported in a positive, equalized and flexibly yielding manner to prevent leakage due to the loosening of one joint causing the loosening of another and so that the joint bolts can be tightened at the top of the header castings.

Superheater Dampers. These should be kept in good operating condition, so that when the steam ceases to flow through the superheater units the products of combustion will stop flowing through the superheater flues, particularly when drifting at high speeds.

Steam Delivery Pipes from the Superheated-Steam Chamber should be made of adequate cross-sectional area to reduce steam-pressure losses and removed from the interior of

the front end, so that no joint where they pass through the front end will be necessary.

Automatic Saturated-Steam Supply When Drifting. This is essential to eliminate the human element and insure a proper supply of saturated steam with the superheated steam just before the throttle closes and continuously thereafter. A jet of saturated steam should also be supplied to the exhaust nozzle to neutralize the gases ordinarily drawn through the same into the valve chests and cylinders.

Modern types of locomotives have developed at low speed 3,000 i.hp. and at high speed 3,200 i.hp., and comparative average water rates through the complete range of the effective capacity of the locomotive, with piston speeds of from 600 to 1,000 ft. per min., have been obtained, as shown in Table 2. At piston speeds of less than 600 ft. per min. the water rate of the double-expansion saturated-steam locomotive will approximate that of the single-expansion superheated-steam locomotive.

TABLE 2—COMPARATIVE WATER RATES OF LOCOMOTIVES WHEN USING SATURATED AND SUPERHEATED STEAM

Cylinders	Steam	Water rate per i.h.p.-hr., lb.
Single expansion.....	Superheated	16 to 20
Single expansion.....	Saturated	24 to 29
Double expansion.....	Superheated	15 to 18
Double expansion.....	Saturated	19 to 22

Compounding. With the exception of the Mallet articulated type of compounding, the multiple-expansion system of steam utilization, which has been so successful in marine and stationary practice, has not made the progress in this country that it has in Europe.

The failure of various types of cross, four-cylinder, four-cylinder balanced and tandem double-expansion locomotives, introduced from 25 to 15 years ago, to produce the predicted economy was due largely to factors of indifferent design, low boiler pressure, excessive condensation, lack of proper maintenance and operation, poor fuel and road failures. Clear-ance limitations also restricted the size and arrangement of the low-pressure cylinders, while at the same time the single-expansion-cylinder superheated-steam locomotives gave opportunity for greater hauling capacity and economy.

The three-cylinder compound has frequently been advocated owing to the allowable reduced cylinder diameters and piston thrusts and a more uniform turning moment, but its use has been deferred owing to central main-rod and axle complications.

There is no doubt but that a properly designed superheated cross-compound locomotive embodies many advantageous features, such as greater starting and hauling capacity per unit of weight, less evaporating surface per indicated horsepower, reduced fuel and water consumption and less boiler repairs, and that it will return to favor for freight service in combination with higher boiler pressures and superheat, due to the necessity for greater drawbar pull and horsepower and for utilizing all superheat before its final exhaust.

By eliminating the disadvantages of the outside valve gears now in use and adding certain improvements for the purpose of increasing the ratio of expansion and shortening the ratio of compression, the tractive effort can be increased at least 10 per cent at all points of cut-off and the fuel consumption reduced 5 per cent through ability to develop the same drawbar pull with a shorter cut-off. Such a change will add greatly to the efficiency of the steam locomotive.

Where compound cylinders are used a steam expansion regulator should be incorporated with the motion gear to effect the automatic independent adjustment of the cut-off for each of the high and low-pressure cylinders for the purpose of obtaining certain cylinder ratios, and at the same time bring the cut-off in harmony at the center of the quadrant. By this means the ratio between the high and low-pressure cylinders, which, for example, should properly be 1 to 3 at starting, can be brought to 1 to 4 at cut-off, thereby

insuring easy exit of the exhaust steam from the low-pressure cylinder and at the same time automatically distributing the work properly between the two cylinders at speed. In this way a compound locomotive of the Mallet articulated type can be made to develop at least 55 per cent of its rated tractive power at a speed of from 8 to 10 miles per hour, when operating at 25 miles per hour, and there will be a gain in tractive power of about 15 per cent at 25, and of about 10 per cent at 30 miles per hour. In fact, a drop in the drawbar pull in a Mallet articulated compound locomotive on account of speed should not materially increase beyond that of a single-expansion engine.

Cylinder Clearance. The inauguration of the use of the inside-admission piston valve and of superheated steam has brought with it the wasteful effects of larger cylinder clearance, due principally to the use of a valve of too large diameter and an indifferent design of valve chest and ports in combination with the cylinder castings. To somewhat overcome this trouble the piston valves were increased in length, with subsequent breakage of castings through the vertical ports, particularly as the result of water from condensation and unstayed flat surfaces.

The use of smaller-diameter piston valves located close to the cylinder and connected with properly designed expanding steam ports will, in combination with improved material and workmanship, correct these generally existing deficiencies.

Cylinder Back Pressure. About 75 per cent of the cylinder back pressure is due to the use of the exhaust steam to produce draft for combustion, evaporation and superheat. Assuming that for every 100 hp. in steam used only 60 per cent is utilized in producing actual tractive power, then 40 per cent is wasted through the exhaust, of which 75 per cent is chargeable to steam and superheat generation.

Much remains to be done in the way of enlarging exhaust-steam openings from the cylinder to the atmosphere and in reducing existing sharp turns, cramped passages and obstructions to the free passage of steam through them; and also in the development of an exhaust stand and nozzle that will combine the advantages of the single and double types. It has been found that by enlarging a $5\frac{1}{2}$ -in. diameter exhaust nozzle to $5\frac{3}{4}$ in., or about 9.3 per cent in area, fuel consumptions have decreased from 15 to 20 per cent, depending upon fuel and weather conditions, and that the locomotive efficiency has been increased from 10 to 15 per cent, depending upon cut-off and speed.

Valves and Cylinders. Inside-admission piston valves, although inherently deficient with respect to water and compression-relieving capacity, have many advantages, particularly for superheated steam, and the application of doubleported valves for low-pressure cylinders has worked out satisfactorily.

Various tests and many years' experience have demonstrated through the better use of steam and the resulting reduction of jerking, pulling and stresses on valve stem and gear, unbalanced pressure, frictional contact, valve and bushing wear, leakage and lubrication, the practical advantages of a minimum diameter and weight of valve with the circumference no greater than the length of a slide-valve port and with every inch of bushing port made effective and designed in conformity with the well-known principles governing the flow of gases so as to eliminate eddies and baffling in the steam flow which occurs in the passages between valve and cylinder.

In addition to reducing the weight of a valve by reducing its diameter, it can be further lightened by using a smaller spool, as experience has proven that with simple cylinders an area of opening through the valve body equal to one-half the area of a single exhaust-nozzle orifice is sufficient to obviate the hammering of the exhaust steam on the valve ends.

With cross-compound cylinders the conditions are even more favorable, due to the receiver pressure. Furthermore, there is still a possibility of considerably reducing weight in bullring and follower designs, which will further reduce the stresses in valve rods and gears that have been found to increase with the speed, cut-off and weight of valve.

There is also considerable opportunity to improve packing rings by locking and putting them in absolute steam balance, preventing exhaust rings from collapsing under compression or being forced from grooves into ports between bridges, and stopping leakage of live steam to the exhaust side of the valve. Extended rods and carriers for the front ends of both valves and pistons have also been found essential to the best results. Two refined-gray-iron packing rings should be sufficient for all pistons, and two-piece one-ring piston and valve-rod packing of a suitable aluminum alloy should be satisfactory. Wherever possible the center line of each cylinder, under normal working condition, should be in horizontal alignment with the centers of the driving axles. All cylinders should be equipped with suitable types of by-pass valves.

Piston Speeds. Frequent errors have been made in not properly proportioning the driver-wheel diameter and stroke of the piston. Slow speed and high ratios of expansion are factors particularly favorable to superheated steam, and piston speeds of from 700 to 1,000 ft. per min. will insure the best results.

Waste-Heat Distribution and Utilization

As a reasonable estimate would show that 40 per cent of the heat in the steam and in the products of combustion is exhausted from the stack, any considerable part of this heat that can be reclaimed for preheating boiler feedwater will add greatly to the overall efficiency of the locomotive and to the saving in fuel. The principal means through which to accomplish this saving, in a practical way, are exhaust-steam heaters and flue-gas economizers, both of which can be readily adapted to a modern steam locomotive.

Exhaust-Steam Heaters. With the many steam-using auxiliaries, such as those for air compressing, boiler feeding, valve-gear operating and electric lighting, which operate when the locomotive is standing, drifting or working, a combination open and closed type of feedwater heater and purifier for the utilization of the exhaust steam from these auxiliaries, supplemented if necessary by steam from the main engine's exhaust, should receive prompt consideration.

From actual service tests of closed types of heaters, made on modern superheated-steam locomotives, using a portion of the main-engine exhaust steam only, it has been found that a feedwater temperature approximating 240 deg. F., or within 15 deg. of the exhaust-steam temperature, can be obtained without interfering with the draft required for maximum steam and superheat generation.

Flue-Gas Economizers. Owing to the high rate of combustion and evaporation and in the process of superheating, much heat is usually wasted, as the gases from which the steam receives its heat must be hotter than the steam itself. The higher the steam pressure the less is the average difference in temperature between the gases of combustion and the contents of the boiler, therefore the slower the transmission of heat the greater the work of the economizer may be. Likewise the lower the efficiency of the boiler will be if it is not supplemented by an economizer.

An economizer will heat the feedwater to a higher temperature than an exhaust-steam heater and will recover most of the waste heat resulting from high steam pressure and high superheat, as it is able to recover low-temperature heat that has escaped from the boiler evaporating or superheater surfaces because the average temperature of the feedwater within the economizer, which should, if practicable, be

brought up to the boiler evaporating temperature, is much lower than the temperature of the water in the boiler.

As locomotive smokebox superheaters, now obsolete, have demonstrated that 50 deg. of superheat may be obtained from flue gases at 600 deg. F., there should be no difficulty in devising a locomotive economizer that will produce very effective results, in combination with high boiler pressures, superheat and draft, without baffling the boiler draft and evaporating capacity. In fact, with an average boiler efficiency of 60 per cent and an economizer efficiency of 50 per cent, the possibility of recovering from 25 to 50 per cent of the stack gas losses and thereby increasing the thermal efficiency of the entire unit is well within the limits of possibility.

DISCUSSION

F. J. Cole (American Locomotive Company) took issue with many of Mr. Muhlfeld's statements. He cited the fact that a modern locomotive will produce a horsepower-hour on less than two pounds of coal to prove that the locomotive is an economical power plant. He stated that the usual design of locomotive boiler is not suited for a pressure of 350 lb. and much remained to be done in the way of designing boilers to safely operate under high pressures. Mr. Cole pointed out that by the use of trailing wheels the boiler design is improved and higher efficiency secured. He thought it doubtful whether increased water volume would add to the efficiency of the boiler, but pointed out that attention should be given to details of domes and throttle valves to prevent water being carried over into the dry pipe. He also stated that while the high cost of coal undoubtedly justified the introduction of devices that increase capacity and economy, the greater maintenance cost resulting from their use must be considered in judging the relative merits of specific devices.

Clement F. Street (Locomotive Stoker Company) questioned the data Mr. Muhlfeld submitted regarding the cost of electric operation and defended the performance of locomotive stokers.

H. B. Oatley (Locomotive Superheater Company) stated that the program of improvement laid out by Mr. Muhlfeld was not entirely practical as regards economy, though almost ideal from the standpoint of the generation and utilization of steam. He stated that with the proper design of boiler a steam pressure of 500 lb. would prove both safe and economical, and stated that condensing operation was not beyond the realm of possibility. Mr. Oatley also expressed the belief that the present method of transmitting power would be superseded by an improved type of construction that would result in the elimination of considerable unbalanced reciprocating and rotating weight and consequently in less rapid deterioration of the rail, the rail bed and the driving mechanisms.

Otto S. Beyer, Jr., stated that the possibilities for economy of the super-power plant, located in the coal district itself and doing away with fuel haulage, should be considered. He believed that speed in railway operation, which in turn would mean faster locomotives, will be required more and more in the future.

E. B. Katte (New York Central) disagreed with Mr. Muhlfeld's conclusions regarding the objections to electrification. He stated that experience had proved that the capital cost was not prohibitive, that electric operation had been demonstrated efficient, economical and reliable for every class of service. He pointed out that electrification increased the capacity of tracks approximately 30 per cent and that while the first cost of the electric installation was higher than for a steam operated road, the operating cost was less with the electric equipment.

George Gibbs (Gibbs & Hill) stated that the author was mistaken in his belief that electric traction had not given the

desired results. More money had been made for the stockholders by reduced operating expenses or by producing new business either by more attractive or more reliable service or by an increase in the capacity of the railway's facilities as a whole.

Mr. Muhlfeld in closing said that in the boiler being designed for higher pressures the largest diameter of the shell, which was made of 1¼-in. plates, was 68 in. This was about as large a boiler as could be handled at present by locomotive builders. Mr. Oatley had referred to 500 lb. pressure. What had limited him in his argument in the paper to 350 lb. was the cylinder temperature, not boiler troubles, and tests made during the past three years had shown that a higher temperature than 750 deg. F would be one that would destroy the cylinders, as well as the packing and bushings.

In the matter of burning coal, to which Mr. Street had referred, he would say that during the past five years he had made numerous tests of the cinders taken from the back of a stoker-fired locomotive and from accumulations in small boxes placed on top of a freight train, and had found that in nearly every case they were unconsumed particles of fuel. The coal was being put through the boiler but was not being burned.

In regard to questions propounded by James H. S. Bates and William H. Wood, he would say in reply to the former that the steam turbine had not as yet been adapted to the locomotive, and to the latter that fireboxes with flexible stays were being eliminated.

TAPERED JOINTS FOR SUPERHEATER UNITS

In superheaters with spherical ground joints a high tension on the bolts securing the elements is necessary to avoid leaks. An interesting type of joint designed to overcome this difficulty, which has been introduced on the Great Northern, is shown in the drawing below. The superheater units have brass sleeves, fitting tightly over the tubes. After the sleeves are in place the ends of the elements are peened out slightly

Type of Joint Used On Emerson-Yoerg Superheater

to hold them securely. The end of the sleeve is finished with a taper of ¾ in. in 12 in. while the opening in the header into which the sleeve is fitted has a taper of 13/16 in. in 12 in. This slight difference in the taper causes a powerful wedging action when the gland is drawn up and insures a steam tight joint. This type of sleeve has been used with excellent results on the Emerson-Yoerg superheater.

WHAT IS WRONG WITH RAILROAD MANAGEMENT?

Complication but no System; Neglect by Railway Officers Causes Loss of Interest by the Workmen

BY FRANK ROBERTS

EFFICIENT transportation depends in part upon well-kept motive power. The physical condition of motive power to effectively do its work depends upon several factors. First, an efficient, able, interested, co-operative official organization; and, second, a well managed, fully stocked and properly equipped enginehouse. The third is further removed from the daily routine, or from direct touch and actual operation. The general locomotive repair shops are truly the general hospitals, in which all real operating disorders are corrected, the source of all emergency heavy repair parts, and the place where the real upkeep is handled.

I make this introduction for the purpose of coming down to the conditions prevailing in railroad repair shops and to show the methods that are tolerated. Extravagant inefficiency, which would ruin Henry Ford if introduced into his shops, is overlooked in railroad shops and covered up with an annual appropriation and forgotten, the same as a wealthy parent makes an allowance to a boy at college and then forgets it. We get some idea of this waste as we read how Uncle Sam lost \$1,000,000 a day while operating our railroads.

From what appears in our daily papers, or what we hear on the street, or observe from the car window, a person gains but little understanding of the necessity for an auxiliary such as a general repair shop for motive power.

This lack of understanding and appreciation on the part of the public is unfortunate and in about the same spirit, it would appear, the railway officers try to forget the shops. The only token that the workers in these shops have of their employer's interest in their welfare is a visit once a week by the paymaster, and perhaps late in the autumn a few workers will drop in unexpectedly and repair some of the worst leaks in the roof over their head, replace missing window lights or otherwise protect them against the approaching cold of winter. This may seem a little unfair to an outsider, but to the workmen themselves the impression is that, with the above mentioned duties performed, the officials have discharged their obligations, and locomotives should always be in fit working order to deliver their allotted ton-miles of service without the sacrifice of a single B.t.u. of heat or mechanical energy through inefficiency resulting from any possible question of repair.

The fact is, about eight per cent of the total investment of a railroad is in locomotives; that is, if the road has been properly financed. Some we know have had their capitalization so doctored up that if all the facts were generally known we would be prone to consider the venture as below water, and a marine rather than an overland proposition. This eight per cent investment unfortunately is like the dresses women wear—more expensive in the first cost; much more care and trouble to maintain and not nearly as serviceable as they were 20 years ago. For example, 20 years ago we could purchase a good locomotive for \$15,000, and today a modern locomotive costs anywhere from \$50,000 to \$100,000. One railroad purchased some Baldwin "hogs" some 20 years ago, and it was usual in rush seasons for these locomotives, after making their daily run, to come into the freight yard

with a train, disconnect, run on the turntable, head about, have the fires cleaned on the ashpit, the tank filled with water, the sand box and coal pocket filled, a new crew on hand who immediately advanced to the yard, attached to a train and made the return trip. These engines have operated under such conditions for a week at a time without ever seeing the inside of an enginehouse. The only repairs or attention they received were made by the engineman and fireman in charge. But that was during the days when everybody knew the division superintendent and all had a semblance of interest in their work. Those were days when a man was allowed to take pride in his work, and he knew that his days with the road were determined by faithful services. At that time common sense kept each worker's ambition up. Unusual ability gave unusual results, and promotion came to the faithful. If trouble came it was local and settled in a man to man fashion, and the public had all their trains during the controversy.

Complication but No System in Handling Work

Conditions have changed, not only in the matter of human relations, but equally noticeably in the motive power. Our

locomotives have become so overgrown that they shake themselves apart on the road, and it is not safe to continue them in service over 100 miles. This may be news to some people who may imagine that the same locomotive draws their

Inefficiency of railway shop organizations due to lack of proper tools and of interdepartmental co-operation, resulting in loss of time and money.

train from Boston to Chicago, but if they will observe the number on the cab as they board the train at South Station, Boston, and observe operations at Springfield, again at Albany and so on at about every one hundred miles, they will see a change of locomotives. The locomotive thus relieved is run into the roundhouse and a crew of men goes over it, making the repairs that the engineman's report calls for, usually considerable, including anything from a mis-set safety valve to a leaky set of boiler tubes. In addition to this there is a staff of inspectors who examine for their special parts. One looks for flat wheels or sharp tires, another for hot journals, another to test the air brakes, lubricators, etc., until every part is thoroughly inspected. If the piston rod of the air pump was leaking in olden times the engineman took about five minutes and repaired it—now he is not allowed to. He must make a report and a special workman is sent out to do the work. He may or may not make a good job of it, but it makes no difference, because another engineman will take the locomotive out on the next trip, and the air pump man in the roundhouse at the other end will give it a try.

An inspector may report a nut off a binder bolt. The machinist finally reads his work report, asks the storekeeper what size bolt locomotive No. 1100 has on her left main binder. He thinks it is a 1-in., his friend is of the opinion that it is $\frac{7}{8}$ -in., and his helper declares it is either $1\frac{1}{8}$ -in. or $1\frac{1}{4}$ -in. because they put some on No. 900 last week. "All right! To be sure, we will take one of each, $\frac{7}{8}$, 1, $1\frac{1}{8}$, or $1\frac{1}{4}$ -in. to save a trip out to find out just what size it is." This plan certainly saves steps, and they proceed into the enginehouse to locomotive No. 1100, and sure enough the

helper was right, it is $1\frac{1}{8}$ -in., and on the nut goes. But it is a waste of time and strength to take those other nuts back to the stock room, and down the pit they go. This shows the modern spirit, and if you are not yet convinced let me state that on one division, where there are only 300 locomotives, the firemen used 2,400 fire hooks in six months, or an average of a hook on each locomotive in 23 days. Where do they go? Of brakeman's lanterns 5,000 a year. Where do they go?

Present day locomotives cannot continue in service even in an emergency without considerable repairing after each trip of about 100 miles. The element of continuous service is a lost art, as well as the spirit of service that came with a day's work years ago.

Inefficient Methods for General Repairs

All the repairs thus far referred to are classified as enginehouse work. After a locomotive has made from 50,000 to 75,000 miles, usually in from 10 months to a year, it is taken out of service and given a general overhauling in the shop. Also all locomotives that have had a serious breakdown or have been in a wreck find their way back to the shop. They are dismantled or stripped, all the parts thoroughly cleaned, broken parts welded or replaced with new, all springs are heated and restored to the original dimensions and again tempered, valve gear and side rods annealed and new bushings applied, the cylinders and steam chests re-bored, or perhaps new bushings applied. The piston and valve stem packing is repaired or replaced, the driving boxes equipped with new brasses and liners, the axles and crank pins turned and trued, the driver wheels turned or perhaps new tires put on, the driving box shoes and wedges refitted or perhaps replaced with a new set and the frames repaired if they are worn or cracked. The boiler must be thoroughly inspected and tested, the flues removed, cleaned and returned and welded in place. The safety valves, injectors, pneumatic firedoors, gages and gage glasses, the air brakes, valves and pump, power reverse gear, electric light generator, the super-heater units, tender tank, trucks and draw gear all require a thorough rebuilding. So much for the extent and nature of repairs which are completed with the locomotive ready for trial and return to service, from which she has been withdrawn for a period varying from 16 to 30 days.

The important connection with all this is the way in which it is handled and the lack of co-operation and interest among the workmen, due in a large part to official neglect and the results of present day tendencies. The peculiar thing about railroad organizations is the fact that no man or any particular job nor any particular person can get any recognition, either for his ideas, the need for necessary material, or is provided with tools or adequate shop facilities to go ahead efficiently. If a man asks his gang leader for a new file or a piece of belting for his lathe he is told that the storekeeper is out of that material. The storekeeper informs the shop foreman that the purchasing agent has had his requisition for three months and has not placed the order, or else he is told that his letter of certain date requests that he hold back on certain items for some months, or under conditions now existing he will have to ask him to cut his stores down another 25 per cent, etc., etc. Perhaps the general foreman has been drawn in and he, through the division master mechanic and the superintendent of motive power, has learned from the general superintendent that he informed the purchasing agent to hold up purchasing anything further until January 1, because the federal authorities were expecting to turn the roads back. All this time the man on the lathe is wondering how he is to do his work, and as a natural result about all he is doing is to keep his time card filled out each day, draw 72 cents per hour, and report to his fellow workman about the loss that the road is experiencing because of

lack of support and interest in the shop on the part of the officials of the company.

Antiquated Tools Cause Loss of Time and Money

I know of a case where it was proved that an improved piston packing ring gave a good many thousand miles of increase in service, over the plain snap rings, and they wanted to adopt them, but there was not a machine available to turn them up on. A new vertical boring mill was requested and the request was backed up with all the facts and the advantages to be gained, providing, as conclusively as argument could, the saving in dollars and in increased service from the packing. But all the satisfaction we obtained was, that there was no money available and no matter how great the savings might be we simply could not make the purchase. The same week a new 60-ton wrecking crane was ordered and most of the time it stands on a siding outside of the shop beside several smaller ones, waiting for service or a wreck.

The railroads will not purchase a new outfit of lathes, but continue to use some over 50 years old and are paying men modern wages to watch those antiquated curiosities feebly fooling away their time trying to do the work before them—meanwhile the operator is resigned to slow death. These same roads do not hesitate to scrap locomotives of 20 years ago and purchase modern ones, calling it good business. This may be so, but why not replace mechanical equipment in the shop that is removed more than twice as far from present day practice? It must also follow that this is just as profitable as the reasoning applied to the scrapping of the locomotives. This critical review can be carried back, in many instances, to show the neglect of railway officers in not keeping up their shops. It is certainly poor reasoning to spend ten dollars for labor when one dollar in tool service and four dollars in labor properly supported could have saved five dollars on the same job, and when this support would restore the interest of the men in their work.

I contend that railroad officials do not properly appreciate or support the repair plants.

Too Much Petty Jealousy

The railroad organizations are so cumbersome that the process of reaching the final authority is worse than climbing the Swiss mountains, and just about as likely to reach the desired end if the attempt is made single-handed by any ordinary workman. Subordinate officials or workmen dare not address a "higher up" directly or off comes his head.

There is too much petty official jealousy in the average railroad make-up. The authority is too far removed to be efficient. Everybody must see his superior and get official authority before he can act and the different departments and divisions do not co-operate properly to make railroad work attractive or efficient.

What we need is greater freedom among local officials. Lift the red tape and restraint from these officials in small matters. Give each man his work with a man's freedom and place responsibility with him for the results. Then support him with proper and necessary equipment and we will at once begin to get a lot of officials that will take on normal development, exercise their own judgment and increase their interest in their work. A change will then take place in the financial showing of all departments. What railroad men require is a greater understanding as to just what the railway officers really want or expect from them, the custom now being to keep away and show absolutely no interest in the shop except for an official visit preceded by due warning that they will come, about 10 days ahead of the time set. The poor local foremen get busy and wash the windows, whitewash the front fence, clean the waste papers from the fence corners about the place and issue instructions to "close off all air pipes in departments A and B next Monday morning until after official So and So has left, for we do not want him to

hear the escaping air (dollars) whistling from some 25 or more air hoist control valves and leaky air pipe lines."

Robbing Peter to Pay Paul

For further illustration, what would you think of management that will defer consideration of making an outlay of \$500 for the purpose of digging up a sewer tile, draining 21 engine pits on the erecting floor where 200 men are engaged every day, and where it is safe to say 10 per cent of the total efficiency is destroyed because of water in the pits?—On this same erecting floor there is but one crane and men wait a whole day to lift a set of superheater units in or out, or the boilermakers stand around four or five hours waiting to transport a set of boiler tubes, etc.—Where another department will come in and rip up the floor under six or eight lathes a week before the new floor lumber is at hand? Where the purchasing agent is 100 miles away from the shop, never makes a visit or gains any first-hand information and permits an engine to remain out of service for want of parts that should always be in stock? I know for a fact of a case where a man in need of an airpump gasket stripped eight different pumps and then had to use one that he felt sure would not last a week, and remarked that the pump will be back soon though it should remain in service for a year. The enginehouse men will not attempt to fix it, but will rip it off and cry for another, and more than this, suppose air brakes fail and a wreck results, the engineman is to blame. Now, who ever heard of a purchasing agent being to blame? How utterly impossible for a purchasing agent to cause a railroad wreck. The nearest that we could possibly connect them would be in providing inferior material or forcing the continuance in service of material which is not safe, because there is no other on hand to be used. Railroads lose thousands of dollars in not keeping stocked up with necessary materials. A cent saved by being withheld from normal requirement in material is a dollar lost in time in too many cases. Suppose a man wants a 1/2-in. nut and spends an hour sorting over scrap to get one that fails and ties up a train for an hour. Or if he wants a 3/4-in. pipe union, the piper strips a pipe off another locomotive and in doing it loses a piece of pipe three feet long, causing a loss of one and one-half hours time spent by the piper and his helper in looking for it and finally making a new pipe and robbing the second locomotive to get this same union back.

In these cases there are several things that an enginehouse foreman may do. He may lay the engine up and keep her out of service, or he may rob from another locomotive. This is practiced altogether too much, for it costs money to transfer parts from one locomotive to another, and it is not a cure for you always have one locomotive left without parts no matter how many changes you make. The expense keeps mounting until a new part finally arrives. By that time the changing around has met with a question of sizes and the part fits on in its original place. Meanwhile the changes have caused the breakage of a second part, which, if the other part had been left on in its original place, would have continued for years. Locomotives are not maintained to a standard close enough for indiscriminate changing of parts without costly breakdowns. A third plan is to send her back into service, if possible, hoping that she will make the other end of the road and there let "George" worry about it.

An enginehouse foreman makes a request for an item of material; the storekeeper looks it over. Suppose it is for eight driving box shoes for a Consolidation locomotive. The storekeeper has instructions to trim this month, so he follows instructions and orders six shoes; the purchasing agent recalls his trimming policy and off go two more. The order is placed for four. Why is it that when they are delivered to the enginehouse foreman he cannot say "Thank you, just as ordered," instead of losing interest and returning the loco-

motive to service with defective shoes and 40 points of defective personal feelings? He sees and knows that results like this are official failures, and that he is absolutely unable to help himself. Inefficiency in the official organization causes discord, loss of interest and expense among the workmen.

Organized Labor Dominates the Situation

As before mentioned, workers were formerly handled as a local problem and each problem had its own solution. Today conditions are different and we must consider our entire railroad system as the unit, and worse than this, various branches or trades are interlocked to bring joint pressure, if necessary, to force their demands, and railroads, under federal control, have never been courageous enough to refuse a real demand thus far.

Organized labor has the railroads by the throat and is, at this time, the cause of heavy losses through open and defiant inefficiency. For example, one shop that I know of used to have two men strip the front end of a boiler complete ready for the boilermakers, and they did it in quick time. Today that same shop has to have an electrician disconnect the headlight wires, a machinist removes the marker brackets and lamps, the boilermakers the front end door plate, spark screen and draft pipes, the machinists take out the exhaust tip and base, the boiler makers the draft plates and the machinists the superheater units and damper mechanism. The hold-up is apparent.

Now, why this organization and its inefficient agreement? Simply the limitations of human endurance. The men could not gain anything until they organized and forced it, but even after recent experiences these same officials will no more recognize a workman who loyally stood by his post and their interests by refusing to go out on a strike, than they do the worst agitator who caused the strike.

Labor organizations are all right if properly handled. We know the parent organization as the American Federation of Labor. Certainly a fine name, and we would expect American standards of patriotism to find expression among their activities. But here is where it seems to fail. I would insist first of all that none but American citizens could hold office within its ranks and all alien members should lose their voting power. No leader or agitator should be allowed to address their meetings or distribute circular matter written by any alien. If I had my way, citizenship would be necessary to gain admission to the membership and all those that are members at the present time would have to become American citizens or get out of the union. Any member engaged in disloyal activity would be expelled. In short, I would make the Federation of Labor an asset to our nation and not the propagating ground for anarchy.

How to Improve Conditions

How can we improve conditions? How can we make the railroads change about and earn not only their operating expenses, but pay a rental for the money already invested as well as to create a condition where real live workmen will take part in the work, and an investor will hazard his money in their care?

The answer is, we must study human nature, and have real live men take part in railroad administration and operation. This is evident when you look at the long line of failures that follow almost every railroad man when he leaves railroad work and tries his hand at other lines. He doesn't last long enough to make it worth mentioning. Why? Because in railroad work he was never placed where he carried any real responsibility. The "higher ups" prescribed his work so completely that he never had a chance to know what personal initiative meant as connected with him. No, he never knew what it meant to shoulder a situation and go

through with it himself, and so it goes, once a railroad man, always a railroad man, unless the "get-away" was quick and he did not fully get into the rut.

What I would like to see is the higher officials to drop their distant, aristocratic, important, special car stuff and get back to first principles, be real men again, and in good democratic fashion have, at least once a year, a banquet, picnic, or get together under any pretence, where every worker could have a chance to see and talk with his officials and listen to a real declaration of purposes and principles. Not the present code that has seeped through the blockade of unwilling chief clerks and department heads. To do this in a free manner implies, of course, that the president or ranking official is all that the job calls for, the real thing and not somebody's son or cousin, who serves as a figurehead. The time is here when we must make our railroads democratic, we must have real live one hundred per cent Americans and practical men who have the capacity for their official tasks. The favored son or relative day is past. Officials must meet, study and understand their men and their needs. They have got to surround their subordinates with an atmosphere of hope, fair dealing and encouragement, which will create conditions for departmental co-operation. There is a world of power in the brains of the workers if their officials will permit it to come to the surface and use it.

Increased Pay Alone Not Sufficient

I am a strong believer in humanity when given encouragement and understanding, and know that increased pay or wages will never satisfy or stabilize workers anywhere. There is not a case in all history where money alone permanently satisfied human nature. It may produce conditions leading to abundant happiness, but of itself alone it only proves in the long run slow poison to manhood and individual advancement.

Robinson Crusoe threw it away. Shylock retained it and threw himself away. William Penn used it and was happy in the service that it made possible for him to render humanity. Labor organizations have constantly asked for more pay and shorter hours, better working conditions and the establishment of restrictions that have reduced the production per unit time at least 50 per cent. The encouragement given to these organizations during past two years has produced a ridiculous disrespect among the members for the very people who must pay the price for all the advantages, as well as those who granted the concessions.

Co-operation and Loyal Service

We are confronted by two problems. Inefficiency and disloyalty, and the charge is up to both officials and men equally. The relations between officials and men are just reversed. The officials seek to forsake and neglect and men try to produce as little as possible. With this condition on our hands how are we to arrive at a solution that will effectually line up all hands for loyal, full 100 per cent co-operation and service?

It must start with the officials, they must have money to purchase shops and equipment, and the men must be brought into a new spirit of appreciation of the importance of full co-operation and respond with loyal service. They can do this by proper mental discipline, forsaking outside discordant leadership, engage so fully in their work that it returns satisfaction from the consciousness of having done well, whatever the task that may be theirs. Make the shop atmosphere an asset so forceful and progressive that the officials will find more pleasure in frequent visits. They will realize that it is better business to keep their individual employees straight by personal contact, than it is to read, in the seclusion of their private office, a cold report of how many bent spikes were straightened at the scrap yard. The salvaging of scrap material is good business, but the keeping of our human factor

above scrap valuations is a better official pastime and when that is realized, there will be, due to a higher degree of interest within the workmen, thousands of dollars worth of material used, that is at the present time dropped into the scrap.

But how are we to break the ice and change relations? Official abandonment has forced organization upon the employees. No better means is at hand to work out this problem than through organization. Organize how? Who? Organize all the employees of a road into one complete family of interest as loyal as a hive of bees, and let the employees have a voice in the management. When the officials need money, issue bonds of low denominations and sell them to their employees. There is all the money they need right at home—why not use this asset which has always been available, and is now. Do not cry poverty, higher transportation charges, etc. Cast off that Rip Van Winkle stuff, and let us see ourselves as others see us. When you accept an employee's money into a business that he is selling service to and has a voting power in, you get his good will, and this is worth more in actual cash to our railroads today than all the money that they measure on the deficit side of their ledgers.

I believe in myself, I believe in the future of our roads, either under private or government ownership, and I believe in our state and nation. But I am not satisfied with present day conditions or relations. I do not believe a body of Congressmen, absolutely ignorant of railroad affairs, can ever furnish the relief we need at this time to place the railroads on their feet. To further illustrate, take any business proposition and put it up to the politicians to solve. I do not think there is one man in Congress out of three and perhaps out of ten who can handle bookkeeping or can audit an account, and how can they pass reasonably on a business proposition, let alone one like the railroads. The solution is not there. Where is it? Among the railroad employees themselves. There is not a man working for any railroad in the United States, in any capacity, but has an honest criticism, and also a remedy. The collection of such material and molding it into a new plan of management will go a long way towards improving conditions all along the line, clear up to a cash balance on the proper side of our books at the close of business each month. Labor will become smoothed out and the railroads will cease to be a national danger and worry. They will furnish the service that will efficiently handle the business of the best country and nation on earth. A fair portion of this profit must come back to the man in "jeans" that has faithfully and steadfastly performed his task, no matter what it may be.

My faith in humanity is my faith in America and the solution of this problem.

A PLUGLESS GREASE CUP

BY J. P. RISQUE

Owing to the loss of 300 grease cup plugs and lock nuts from locomotive side rods, the mechanical department of the Florida East Coast Railroad has produced a design which has been tried on three locomotives for some time and promises to eliminate the losses referred to.

The attachment, as illustrated in the drawing, is intended

Plugless Grease Cup with the Filling Apparatus Attached

to be used on cups which are forged as integral parts of the rod. The outside threaded cap A is turned from a solid bar of soft steel and is made to screw into the rod cup very tightly. It is provided with a cup approximately 3/4 in.

and screwed down, forcing the grease through the filler hole against the ball and down into the cup. When the cup is filled the filling shell and its plug are removed.

The favorable reports on the performance of this cup warrant its adoption as standard by the Florida East Coast. The reports show that the first cost of the device is more than offset by the savings it has brought about, not only by eliminating the loss of plugs, but by a considerable reduction of side rod brass losses due to running hot.

ONE-PIECE CAST STEEL FRAMES FOR ELECTRIC LOCOMOTIVES

A notable example of the large and intricate parts which are successfully made of cast steel is the bed casting for the latest order of electrical locomotives built for the New York, New Haven & Hartford, illustrated herewith. In designing this locomotive the weight of the built-up frame was found to be so great that the total weight would exceed the allowable limit. For that reason the Commonwealth Steel Company, St. Louis, Mo., was asked to submit a design. The general plan for such a casting had been worked out by the company's engineering department, but the 10 beds for the New Haven locomotives were the first to be made.

The locomotive bed is 32 ft. 4 in. long, weighs 17,000 lb. and is probably the most difficult casting of its kind ever attempted. This single unit replaces a very large number of parts, greatly reducing the weight and increasing the strength. Numerous bolts and nuts have been eliminated that become loose and allow play, especially at the pedestals. This will result in a considerable saving in the cost of maintenance and repairs. This locomotive bed strikingly illustrates the adaptability of cast steel to certain types of construction. It not only provides an irregular contour of members for clearance without sacrificing strength, but also facilitates securing various cross sections of all members, correctly proportioned in size to correspond with various

Cast Steel Bed for New Haven Electric Locomotives

deep by 1 1/2 in. in diameter to contain the grease. The base of the coil spring, shown in section, is seated on a steel pin which is driven through from the side of the cup in the position indicated. The expansion of this spring seats the ball against the top filling hole, closing it.

The filling apparatus consists of a special shell B and its force plug C, the former being screwed on the projection of the cup. The shell B is filled with a section of grease cut to the necessary size to prevent waste and the plug inserted

stresses, at the same time providing the required flexibility in the structure.

During the months of January and February the Railway Age reported orders for 364 locomotives, 8,616 freight cars and 60 passenger cars for domestic service. There were also ordered 268 locomotives and 1,560 freight cars for export. In the week ending February 27, 207 locomotives were ordered for domestic service.

PRAIRIE TYPE LOCOMOTIVES FOR THE KIN-HAN

The Lima Locomotive Works has recently built for the Kin-Han Railway of China ten 2-6-2 type locomotives to be used in mixed service. This road runs from Pekin to Hankow and because of track conditions a number of difficult engineering problems had to be met in the design of these locomotives. There were very close limitations of weight for both the engine and tender. There were also rigid requirements in connection with the counterbalancing of the reciprocating parts and the locomotives were required to pass over 22-deg. curves. To meet these conditions and produce a satisfactory design of locomotive required great care in designing and construction. The engines have been built and fully meet the requirements in all particulars.

The limitations of weights made it necessary to design all the parts as light as possible, consistent with the proper strength. The built-up type of construction of plates and angles was freely used in the main frames and the tender frame bracing wherever it was found that such a construction could be satisfactorily employed. Care was taken to produce a symmetrical, clean looking design and wherever it was feasible the parts were made in one piece. For example, the guide yoke and the link supports were made in an integral casting, thus eliminating bolted connections and reducing the weight of the parts.

The limit for the dynamic augment at a speed of 50 km. (37.3 miles) per hour was specified at 15 per cent of the

coal capacity of 13,300 lb. The water capacity of the tender is 4,800 U. S. gallons.

Great care was necessary in making the tender design to meet the limitations of axle load as given in the specification. In general, the locomotive was designed along the lines of American practice and the builders were given a free hand in the construction of details so long as they were kept within the limitations of the specifications. The general dimensions of the locomotive, as well as the actual weights as compared with the weight limitations specified are given in the following table:

ENGINE		
	Actual weight	Limit of weight
Front drivers	32,600	33,000
Main drivers	32,600	33,000
Back drivers	32,000	33,000
Total drivers	97,200	99,000
Engine truck	28,400	28,500
Trailing truck	30,400	31,300
Engine, total	155,000	158,800
TENDER		
Front wheel	30,400	30,800
Middle wheel	30,600	30,800
Back wheel	30,600	30,800
Total	91,600	92,400
General Data		
Gage	4 ft. 8½ in.	
Service	Mixed	
Fuel	Soft coal	

Prairie Type Locomotive for Service in China

static wheel load. In order to come within these requirements and at the same time provide the proper counterbalance, the reciprocating parts were made of very light design and a special method was employed to secure an exact adjustment of the counterweights in the driving wheels. The dynamic augment requirements were met and by means of careful adjustment the proper counterbalance was secured for the reciprocating weights.

The boiler is of the extended wagon top type, radially stayed and fitted with a combustion chamber. The locomotives are equipped with superheaters and the reversing mechanism is of the Lawson patented screw type, which provides for easy operation and is fitted with a positive locking device and an indicator which shows the exact cut-off at which the engine is operated.

The tender is of the six-wheel, rigid wheel base type, with plate side frames, the journal boxes working in pedestals riveted to the outside plates of the frame. The two rear pairs of wheels under the tender are equalized. The tender tank is 20 ft. 8 in. long by 9 ft. 8 in. wide by 4 ft. 2 in. high inside, and is built up of ¼-in. steel plate reinforced with 2½-in. by 2½-in. by 5/16-in. angles. The coal space is 4 ft. 9 in. wide and is 6 ft. 2 in. long at the floor, extending back on the slope sheet for a distance of 5 ft., giving a

A Longitudinal Type of Repair Shop.

MODERNIZING FREIGHT CAR REPAIR FACILITIES*

A Presentation of the Several Phases of This Subject and a Proposed Shop and Yard Layout

BY GUSTAVE E. LEMMERICH
Layout Engineer, The Austin Company, Cleveland, Ohio

THE TREMENDOUS industrial growth of our country, its railroad traffic and its foreign commerce has created a need for a transportation machine which will not only meet these demands but also keep abreast of the times. It has been estimated that there is an urgent need for 700,000 new freight cars; but even if this is true, it will be practically impossible to obtain delivery of such a large number for several years, as there is at the present time an insufficient manufacturing capacity. The total existing freight car equipment consists roughly of about 2,500,000 cars. If

more net revenue than the purchase of new cars. Undoubtedly, a combination of the two means relief will be necessary to bring about the desired results.

In 1917 about twenty-nine million cars received light repairs and about two million cars received heavy repairs, i. e., practically every car was sent in for light repairs once a month, and about 80 per cent of the total equipment underwent heavy repairs once a year. For the past four years the average cost of these repairs has more than doubled. The weighted average cost of freight car repairs, computed

A Paint Shop of the Transverse Type

facilities are provided for obtaining the maximum road service from these cars, quicker relief will be afforded perhaps than could be secured by waiting for the delivery of all the new cars needed. For instance, statistics recently compiled by competent operating officers show that the average car-miles per day on several important roads have varied from 25 to 37. Any improvements which will bring the low average nearer the high average of car-miles per day will produce

from an article on "The Maintenance of Freight Equipment" by L. K. Sillcox, on page 657 of the November, 1919, issue of the *Railway Mechanical Engineer*, was about \$79 per car in 1916 and \$170 in 1918. These costs were based on about 500,000 cars. This increase was due in general to the high cost of materials and labor, the construction and condition of the cars, and the lack of proper facilities for making efficient repairs. It does not appear that the first item will change much for some time, but it is probable that labor costs will

*Copyright by Gustave E. Lemmerich.

decrease, due largely to increased efficiency. This combination of high costs and ever-increasing traffic calls for prompt improvements in handling all car repairs, and particularly affording a means of making light repairs independent of weather conditions.

Making Needed Improvements

There is an apparent tendency toward better and stronger rolling stock, designed to withstand the heavy strains of long

train and yard operation. Old, weak equipment should be reinforced or assigned to a class of service in which it may still be useful, or it should be scrapped. All underframes in heavy freight service should be of steel.

It does not appear that the seriousness of the car situation lies so very much in the present needs for a large number of new cars as in the immediate demand for proper

facilities for repairing and modernizing the present equipment, and for the pushing of other improvements which will tend to better car movements at the terminals and on the line. Inasmuch as those facilities are so closely interwoven with the freight car situation, an outline of some of the important suggestions, which will tend to improve the car situation, may not be amiss:

(d) Improvements of terminals, varying from some minor betterments costing only a few thousand dollars, to vast projects, such as detour lines around the great congested traffic centers.

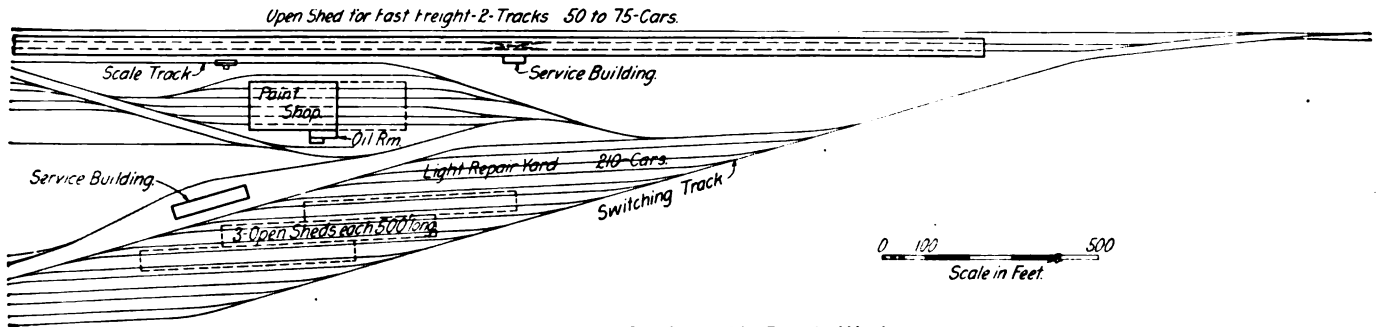

(3) *On Line.*

Other improvements, such as additional tracks, automatic block signaling, etc.

(b) Important changes resulting from the consolidation of railroads, creating new steam traffic lines.

All of these improvements would greatly facilitate car movements, and they would result in returning cars much quicker, so as to increase their earning capacity. For example, if these additional betterments would result in only a 10 per cent earlier return, it would mean at least a reduction of about 8 per cent in the number of cars needed to relieve the present shortage.

considered, its size, the empty car movements, the available and suitable site, the labor conditions and the material market, etc. In former years, when the mills and the lumber yards were of greater importance in freight car repairing, the main car shops were, in many instances, located at the general repair shop plant of the system, only a few railroads selecting separate locations. The freight car repair shop organization is so different in its character and functions that there is no advantage in having it at the general repair site, except

Shed Group for Open Air Repair Work

A tentative estimate of the new freight cars required in the next three years calls for about 700,000, or about 230,000 cars per year. Eight per cent of the yearly requirements would be about 18,000 cars. At an average cost of \$2,850 per car, this is equivalent to a total cost of \$51,300,000. Capitalizing this sum at 10 per cent for interest, deprecia-

tion, etc., will provide a fund of \$513,000,000 available for these improvements. This sum would go a long way toward paying for most of the improvements suggested.

that both should possess all the particularly favorable points affecting construction and operation. On the larger railroads the traffic conditions are often so greatly divergent in character that, in order to save empty car mileage and to return the cars quicker to their earning power, it might be advantageous to divide the car repairing

Interior of the Longitudinal Type Shop

tion, etc., will provide a fund of \$513,000,000 available for these improvements. This sum would go a long way toward paying for most of the improvements suggested.

General Freight Car Repair Shop Requirements

The question of the location of car repair shops is chiefly dependent on the dominating traffic characteristics and on the prevailing local conditions of the particular railroad con-

between district shops. This division could be extended to provide separate repair shops for steel cars and for wooden cars, each located at the most suitable place.

The layout should embody the principle of a continuous mill operation, the materials entering as much as possible at one end, and the building and organizations so grouped as to avoid any conflicting movements. Such an arrangement is indicated in the tentative layout accompanying this

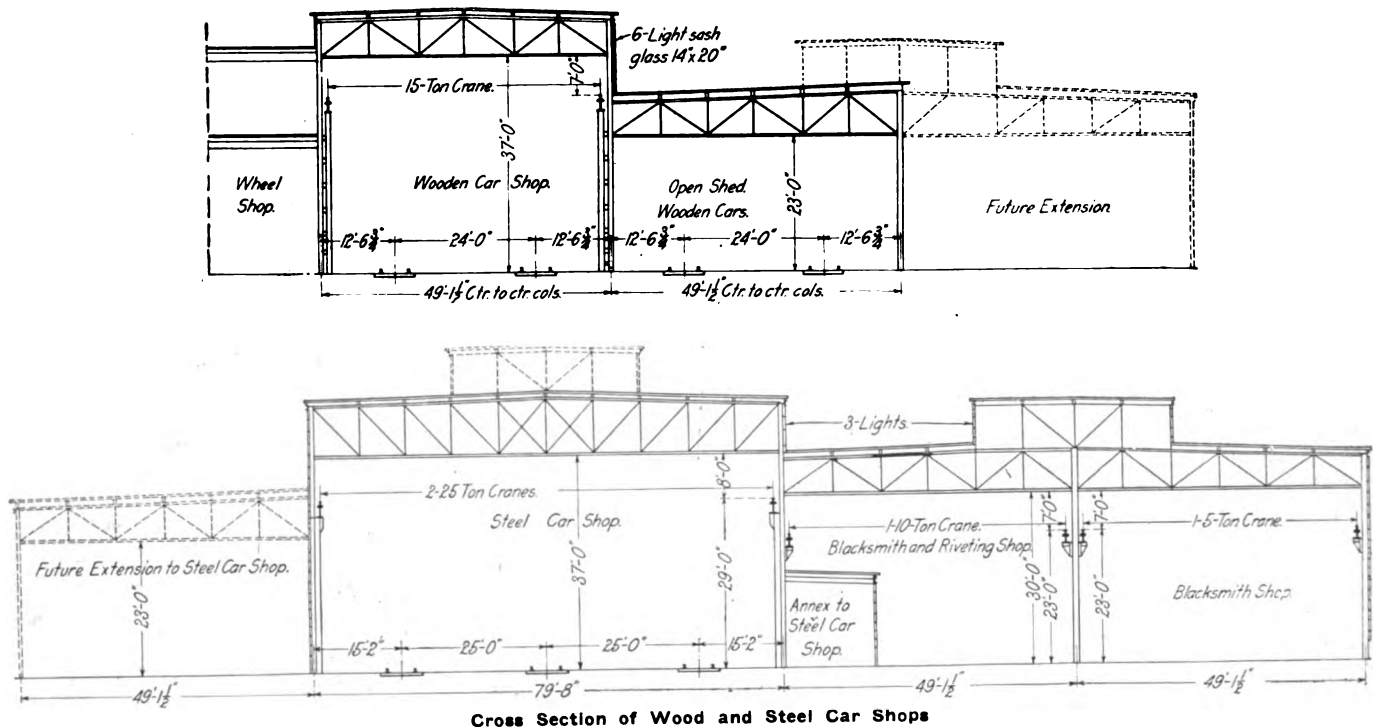

article. The principal buildings should be all under one roof, effecting a saving of a large amount of unnecessary travel and adding greatly to the efficiency of operation.

All buildings should be commensurate to the purpose they have to serve, i. e., they should be of a substantial character, void of all fads, but equipped with all modern facilities. Inasmuch as these structures require large areas, standard dimensions should be adopted wherever possible to reduce the cost and to shorten the time of construction. Such standards should cover the width of the buildings, the vertical clearances, and the column spacing, etc., due consideration being given to the local and operating requirements. The track centers should be such as to give a good workable aisle width, a feature which is of special importance in steel car shops on account of the space needed for the riveting furnaces. This applies to the tracks besides the building walls, as well as to the interior aisles. The buildings should be well lighted, heated and ventilated, and should be provided with cranes wherever they will result in better and more efficient operation.

In former years the wood mill was one of the pivotal features in the layout, but now that wooden underframes are practically a thing of the past, so far as new work is concerned, this department has lost its importance, and a comparatively small building with a few tools is all that is required. The mill, however, should have as an auxiliary a finished lumber shed. The lumber yard has also shrunk to comparatively small proportions.

Auxiliary Building and Equipment

The storehouse with its platforms should be located centrally and conveniently. The building should be of reinforced concrete, provided with a full equipment of bins, an office, etc. The scrap platform in a freight car repair plant is of great importance and should be readily accessible for the delivery of scrap and for the forwarding of it to the blacksmith shop. This platform should also have facilities for the handling, cutting, sorting and storing of all grades of scrap, and a shed for housing some of these should be provided. The other auxiliaries to the storehouse should

Cross Section of Wood and Steel Car Shops

In general, car repair shops are located in or near large freight yards and, in most cases, on filled ground. These conditions, together with the fact that car repair plants are frequently built outside of cities, render it advisable to make the buildings of steel frame construction with walls practically entirely of glass. Where the application of glass is not desirable, such as at the corners and below the windows, asbestos-covered corrugated metal or some other permanent wall substitute should be used. The use of brick should be limited as much as possible or eliminated entirely in order to simplify the construction. The roof can be built with wooden purlins and 2-in. dressed and matched roof boards, the under side being whitewashed to serve as a fire retardant.

A dirt floor appears to be all that is needed in the buildings used for the steel car departments; this can also be used for the wooden car shops in order to reduce the initial cost. If, later, it should be found desirable to have a floor in the wood car shop, old car sills can be used advantageously. In the mill, the wheel shop, and the tool room, the use of creosoted wood blocks laid on a concrete base will be found to be satisfactory, while concrete floors are most frequently used in the storehouse, locker and toilet rooms.

include storage places for wheels, steel plates, angles, beams, castings, etc., and coal, coke and iron sheds for the blacksmith shop. The ground for these storages should be, above all, dry and well rammed with slag.

If this plant is isolated, it will require a fully-equipped power house. If, however, the plant is attached to or near an engine terminal or some other shop layout, the need for a power house is entirely dependent on the respective local conditions. A very important piece of equipment, usually installed in the power house, is the air compressor, which is generally of too low a capacity to meet the present increasing demands. The main shop buildings should have provisions for offices, lockers, wash rooms, toilets, etc., and other plant requirements, such as drainage and sewer system, a water supply and fire protection system, a lighting system, an air piping system, telephone and telegraph connections, if desirable, and finally the necessary yard tracks, etc.

Equipment and Tools

The shop should be fully equipped with modern tools and machines to do the work for which the plant is intended. The power equipment should be on liberal lines, especially

the air compressors. In specifying them, it should be considered that some light repairing may have to be done outside of the regular working hours.

Crane service should be provided wherever it will be economical, and the use of cranes should be extended outside of the building in order to facilitate the handling of material from the yard and to serve in repairing cars during that period of the year when the work can be done on the outside. Such an application will decrease the amount of the fixed charges per car repaired, resulting from the cost of the complete shop plant. The cranes in the steel car shop should have a capacity of 25 tons. In any important layout two should be installed which, when working together, can manage a 150-ton capacity car. In the wooden car department, cranes of 15 tons' capacity will be sufficient. The installation of cranes in the auxiliary departments depends, of course, entirely on their importance. A large locomotive crane is generally a good paying investment, because it combines the handling of material and the switching of cars in one unit. Of late a powerful tractor has been found to be a useful piece of equipment for transporting all classes of material about railroad shops and yards.

This article is confined to a repair shop with some rebuilding, so that the repairing functions, being in preponderance, govern the character of the layout, organization and equipment. The great importance to some roads of having most of its car equipment provided with steel underframes might make it advisable to enlarge the repair shop riveting department, so that some or all of the new steel underframe work of the system could be undertaken. Such an arrangement might stabilize the work and organization of this shop, and will only require a somewhat longer building and few additional tools. Local conditions might make it desirable to have a restaurant, reading rooms, etc., connected with this plant. These could be located in a service building back of the power house. Part of the ground surrounding this building could be treated in some pleasing way for recreation, etc.

A plant serving a district was selected for the tentative layout because shops of this type are particularly suited to meet the present needs; moreover, they conform better to economical freight car operation because their location would result in a minimum empty car movement, yet they are large enough for economical operation.

The Tentative Layout

The plan represents a repair shop with a capacity of about 9,000 cars per year, and provides separate shops for wooden and steel cars, connected by a wheel shop with a crane that will transfer the material between the two shops. It is assumed that this plant is located in a terminal, with its entrance, the yards for the shop and the light repair work directly behind the cripple tracks near the hump on the main traffic yard, or beside one which would be a starting point for the majority of empty car movements.

Of course, this layout must be arranged to conform with the existing local or other traffic conditions, but it must still retain certain vital principles. These include a departmental plan of the yard and buildings, so that the movements of the material are such that the entire plant is on the continuous mill principle, and an interchangeability of the two yards for both the shop and the light repair yard. The buildings for fabricating the materials used in car repairs, such as the mill with its lumber shed, the blacksmith shop, the storehouse, etc., are entered first in the operating plan. With the exception of the mill, the power house and the paint shop, all buildings are under one roof, and this, taken in connection with the crane service, as outlined later, should greatly facilitate the car repairing.

The wooden car shop proper is 50 ft. wide by 300 ft. long, with a capacity of 32 cars, assuming 50 ft. as the length required per car when undergoing repairs, and contains two

tracks and one 15-ton crane. The crane runway extends outside of the building, bringing 8 cars under crane service. Adjoining this shop is a covered shed holding 12 cars. The steel car shop is 80 ft. by 520 ft. in area, and contains three tracks, holding a total of 27 cars, which are served by two 25-ton cranes. One track is cut to permit the placing of a large furnace and some tools in the bay, so formed in order that the crane can carry large sections of damaged steel to the furnace, to the tools and back to the car proper.

In the car shops the distance from the top of the rails to the under side of the trusses is fixed at 37 ft., and to the top of the crane rail 29 ft. and 30 ft., respectively, for the steel car shop and the wooden car shop. This height will permit the handling of side plates, etc., of steel cars of considerably higher and greater capacity than are now in use.

The blacksmith shop is located in two aisles, one adjoining the steel car shop at the furnace section, so as to bring it into the blacksmith shop organization. The riveting shop adjoins the steel car shop, but is at the finished car end of the building; its width also being 50 ft., with its length dependent on the amount of new steel underframe work assigned to it. Both of these auxiliary shops are equipped with cranes. The wheel shop proper is 50 ft. wide by 260 ft. long, with two side aisles, each 30 ft. wide, one containing the tool room, which is back of the storeroom and directly connected to it; the offices and some minor machine tools, etc., while the other aisle contains the fan rooms, lockers, wash rooms and toilets.

The paint shop is situated beyond the other shop buildings and is a well-lighted building, with posts between each track, with dirt floors, and with pits under two of the tracks. The size of this building is assumed to be about 100 ft. wide by 200 ft. long, with a fireproof oil storage room in the form of an addition to it. In case it should be preferred to paint some parts or all of the steel cars in the steel car shop, the paint shop could be greatly reduced or omitted entirely for the time being.

At the farthest end of this layout there are a few yard tracks to accommodate the cars from the other hump.

An approximate estimate of the cost of the freight car repair shop, as indicated in this layout, is as follows:

GRADING AND TRACK			
	Cost		Per cent of total
Grading and drainage.....	\$44,000		3.5
Track	91,000		7.5
Total	\$135,000		11.0
BUILDINGS			
Wood car shop, covered shed and crane runway	\$65,000		5.5
Mill and finished lumber shed.....	24,000		2.0
Wheel shop, tool room, etc.....	68,000		6.0
Steel car shop, blacksmith and riveting shops, crane runways	220,000		18.5
Storehouse platform, scrap platform, etc....	40,000		3.0
Paint shop	35,000		3.0
Power house, including coal and ash handling, stack, etc.....	72,000		6.0
Miscellaneous—Water supply, fire protection, sewerage, plumbing, walks, etc.....	36,000		3.0
Total	560,000		47.0
EQUIPMENT			
Tools	\$165,000		14.0
Power house	115,000		9.5
Cranes	105,000		8.5
Total	385,000		32.0
MISCELLANEOUS			
Cost of land, interest during construction, engineering and contingencies.....	120,000		10.0
Grand total	\$1,200,000		100.0

The fixed charges on \$1,200,000 at 12 per cent per year would amount to \$144,000.

These improvements should result in a reduction in the cost of repairing per car, and in a reduction in the time consumed in having these repairs performed. Assuming a 10 per cent saving in the repair account which, at an average

cost of \$170 per car, would amount to \$17, or, on 9,000 cars per year, would amount to \$153,000, or more than enough to finance the improvements. In addition, the time saved by a plant of this kind in returning cars to their earning power more promptly, also represents a money saving which can be used for financing other improvements.

The Light Repair Yard

There appears to be a tendency in the development of light repair yards to cover a part of the tracks to protect the repairmen against inclement weather. If this is applied along reasonable lines, it will promote more efficient and quicker car repairing, and, at the present rate of wages, will also prove to be a paying investment. If this should run to the extreme, however, it might result in an entirely different type of layout for the light repair yard. Perhaps it might tend to enlarge the sphere of the repair plant and make it necessary to provide a series of open sheds beside the repair shop buildings.

In this layout the light repair yard consists of 14 tracks of 15 cars each, arranged in pairs on 22 ft. and 28 ft. centers, thus permitting an open shed, when so desired, for the storing of material, pipe lines, etc., which could be about 500 ft. long and cover 20 cars each. The material storage shop, a storeroom, an office and the locker, wash and toilet facilities, are located at the ladder track toward the main shops. The switching is done from the ladder on the other side of the yard, so that this ladder is only used in emergencies. The size of these facilities is dependent on their importance and the local conditions prevailing at the terminal. An approximate estimate, which includes three open sheds, each 500 ft. long, theoretically covering 60 but practically 75 cars, is as follows:

	Cost	Per cent of total
Grading and drainage.....	\$40,000	
Track	85,000	
Total	\$125,000	53.0

	Cost	Per cent of total
Service building, including plumbing.....	\$15,000	
Equipment, fire protection, etc.....	15,000	
Total	30,000	13.0
Three covered sheds, 500 feet long.....	45,000	19.0
Miscellaneous—Cost of land, interest during construction and contingencies.....	35,000	15.0
Grand total	\$235,000	100.0

Fixed charges on this investment at 12 per cent equals \$28,200 on 80,000 cars a year, which is the average number such a yard should handle, and it will result in a cost of about 35 cents per car receiving light repairs. The open shed represents about 19 per cent of the total cost.

An Open Shed for Through Freight

The tentative layout also indicates an arrangement for an open shed for fast through freight trains, which will tend to facilitate inspection, the testing of air and some very light repairing under all weather conditions, thus decreasing the chances for delays at the terminals. However, local conditions might make it advisable to place these sheds at some other point. The layout is for two tracks, each holding 56 cars 42 ft. long. A diamond cross-over at about the middle of this shed permits a single track operation when required, and about two 22-car sections may be set for very light repairing. For this layout the size of the shed was assumed to be about 40 ft. by 2,260 ft., with posts set 22 ft. apart on center. The construction is of wood, and the shed should be provided with air pipes and a small shelter in the center for an office, a few tools and the toilets, etc. An approximate estimate of the cost is as follows:

Open shed and small service building annex.....	\$56,000
Air piping, few tools and diamond cross-over.....	5,000
Miscellaneous	4,000
Total	\$65,000

The fixed charges at 14 per cent per year would amount to \$9,100. Assuming this shed will be used by 100,000 cars per year, the fixed charges per car will be 9 cents.

Committee on Standards for Locomotives and Cars, United States Railroad Administration

Bentley, superintendent motive power and machinery, Chicago & North Western; J. E. O'Brien, superintendent motive power, Missouri Pacific; J. T. Carroll, general superintendent, maintenance of equipment, Baltimore & Ohio. Top Row—Standing (Left to Right): H. Zalkind, stenographer; J. W. Small, mechanical assistant to regional director, Southern Region, U. S. R. A.; E. A. Woodworth, secretary; H. Ingersoll, mechanical assistant to regional director, Eastern region, U. S. R. A.

THE INSPECTION OF FREIGHT EQUIPMENT

Defects of Couplers and Related Parts; Federal Requirements for Safety Appliances Summarized

BY L. K. SILLCOX

Master Car Builder, Chicago, Milwaukee and St. Paul

COUPLERS must be in good condition as regards wear and operation of parts, and should be within the minimum and maximum heights as provided by the rules of interchange. Couplers that exceed the distance of $5\frac{1}{8}$ in. between the point of the knuckle and the guard arm, measured perpendicularly to the guard arm, must have the defective part or parts renewed to bring the coupler within the limits of the gage.

Couplers measuring less than $9\frac{1}{4}$ in. from the inside face of the knuckle to the striking face of the coupler horn should not be applied in repairing foreign cars. This should not be construed to mean that a coupler with $9\frac{1}{4}$ in. dimensions may be substituted for the MCB temporary standard type *D* or 6 in. by 8 in. shank coupler. It is necessary to stencil cars equipped with the *D* type of coupler in order to protect them against substitution of the present type with 5 in. by 7 in. shank.

Height of Couplers

Empty cars measuring $32\frac{1}{2}$ in. or less from the top of the rail to the center of the coupler shall be adjusted to $34\frac{1}{2}$ in. or as near as practicable thereto, but not exceeding $34\frac{1}{2}$ in. Loaded cars measuring $31\frac{1}{2}$ in. or less shall be adjusted to $33\frac{1}{2}$ in. or as near as practicable thereto, but not exceeding $33\frac{1}{2}$ in. When the construction of the car and the trucks precludes the common methods of adjusting coupler heights, such as raising the truck center plate height locally on top of the truck bolster, or placing fillers on top of or below the spring seats, the application of metal shims between the journal boxes and arch bars will be permissible. The use of liners between the male and female portions of center plates is prohibited where the vertical bearing surfaces are reduced by the insertion of such liners.

Couplers which are not within the limits of $31\frac{1}{2}$ in. to $34\frac{1}{2}$ in. from the rail not only constitute defects according to the rules of interchange but are also in violation of the requirements of the Safety Appliance Act.

Normal Clearance for Freight Car Couplers at Top and Side of Shank

In fitting up couplers in freight equipment cars it should be arranged to have $1\frac{1}{4}$ in. clearance on each side, that is, between the outside face of the shank and the inside face of the draft sill. The clearance between the top of the shank and the under side of the opening in the end sill is to be $3/4$ in.

Cotter Keys in Knuckle Pins

Cotter keys are not to be applied to knuckle pins and couplers on cars other than hopper and fixed end gondolas.

Uncoupling Lever Connections Short

One of the very serious and easily avoidable items to be considered by inspectors is any lack of clearance causing restricted movement of the uncoupling connections so that when couplers take the full amount of slack possible the lock is lifted causing break-in-twos. This is often due to parts of the uncoupling mechanism becoming distorted and bent.

Third of a series of articles on this subject by Mr. Sillcox. Copyright by the Simmons-Boardman Publishing Company.

Coupler Yokes or Tail Straps

Coupler yokes are to be gibbed wherever possible to neatly fit the end of the draw bar butt and thus relieve the rivets of as much shearing stress as possible.

Coupler Yoke Rivets

The standard of practice for new car equipment and new couplers is to use $1\frac{1}{4}$ in. diameter yoke rivets. However, there are a number of couplers now fitted with $1\frac{1}{8}$ in. diameter rivets requiring repairs at shops where these couplers can be reamed out to take the standard size, and this should be done. At shops where there are no facilities for changing couplers to take the larger sized rivet, it will be admissible to apply the smaller size. Also, when foreign cars appear on repair tracks which are fitted with $1\frac{1}{8}$ in. diameter rivets, the same size can be reapplied.

Coupler yoke rivets should be headed on opposite sides; that is, one rivet will be headed on one side of the yoke and the other rivet will be headed on the opposite side of the yoke.

Coupler Carry Irons

All coupler carry irons must be held in place by at least four bolts if placed vertically and one through bolt with the necessary casting if placed laterally, all securely fastened in place. On wooden draft timber system cars, coupler carriers are to be gibbed or turned up on the ends to avoid the draft sills splitting or breaking away.

Safety Appliances

All safety appliances should be closely inspected and known to be in proper condition, and if not, prompt and proper repairs should be made, remembering especially that couplers must not measure more than $34\frac{1}{2}$ in. from the top of the rail to the center line of the head or less than $31\frac{1}{2}$ in. when the car is empty. Any defects or combination of defects which would cause a coupler to be inoperative, hand brakes, hand-hold, sill steps or other parts to be found uncovered in the rules relating to the inspection of safety appliances must be carefully considered. Passenger train cars used in freight or mixed service must be fitted with uncoupling attachments operative from the left hand side of the car to conform with the rules for freight cars.

Cars, whether loaded or empty, having safety appliance defects must have such defects repaired immediately upon discovery and will not be offered in interchange. If it is necessary to move the car to the shops for repairs of safety appliance defects, it must be moved to the shops of the company upon whose line it became defective.

Equipping Cars with Safety Appliances

Close attention is essential in the matter of giving proper attention in the equipping of cars with safety appliances, both foreign and system. Whenever system cars are loaded and it is found they are not equipped with safety appliances, if routed to some foreign railroad, the routing and destination must be ascertained so that the matter can be taken up with the foreign railroad to have them equip our cars. We must also equip foreign cars on our road, rendering a bill against the owners for the expense of doing the work.

Hand Brakes

Each car shall be equipped with an efficient hand brake, which shall operate in harmony with the power brake thereon. The hand brake may be of any efficient design, but must provide the same degree of safety as the design shown on Plate A of the Safety Appliance Standards.

Brake Shaft

The brake shaft shall be made of wrought iron or steel not less than $1\frac{1}{4}$ in. in diameter, without weld, and provided with a drum and trunnion. The drum shall not be less than $1\frac{1}{2}$ in. in diameter and the trunnion not less than $\frac{3}{4}$ in. in diameter. The shaft is to be held in position with a cotter key or ring. The upper end of the shaft is to be arranged to hold the brake wheel with a square fit, not less than $\frac{7}{8}$ in. and of a nominal taper 2 in. in 12 in. and is to be threaded to such an extent as to provide for not less than a $\frac{3}{4}$ in. nut. The end of the shaft shall be riveted over or held in position by a lock nut or suitable cotter to secure the nut.

Brake Chain

The brake chain shall be made of wrought iron or steel, not less than $\frac{3}{8}$ in. in diameter with a rod link of not less than $\frac{7}{16}$ in. and is to be secured to the brake shaft drum by a hexagon or square head bolt, not less than $\frac{1}{2}$ in., the nut of which must be securely riveted over.

Brake Shaft Seat or Step

The brake shaft seat or step shall be held in position by a stirrup of such design that it will not permit the brake chain to drop under the shaft, U-shape preferred.

Brake Step or Foot Board

If a brake step (foot board) is used, it shall be 28 in. in length. The proper clearances for this brake shaft must be provided so that the outside edge shall be not less than 8 in. from the face of the car and not less than 4 in. from a vertical plane parallel with the end of the car, the 4 in. measurement to be taken from a line passing through the inside face of the knuckle, when closed, with the coupler horn against the buffer block or end sill. The brake step is to be supported by not less than two metal braces, having a minimum cross-sectional area of $\frac{3}{8}$ in. by $1\frac{1}{2}$ in. or equivalent securely fastened to the body of the car with not less than $\frac{1}{2}$ in. bolts or rivets.

Brake Ratchet Wheel

The brake ratchet wheel must be not less than $5\frac{1}{4}$ in. in diameter, with not less than 14 teeth, and is to be secured to the brake shaft by a key or square fit. If secured by a square fit, it shall be not less than $1\frac{5}{16}$ in. square. Provision must be made to prevent the ratchet wheel from rising on the shaft and disengaging the brake pawl.

Brake Shaft Support

When the brake ratchet is more than 36 in. from brake wheel an extra support must be provided to support the extended upper portion of the brake shaft and the extra supports shall be fastened by not less than $\frac{1}{2}$ in. bolts or rivets.

Brake Pawl

The brake pawl shall be pivoted upon a bolt or rivet not less than $\frac{5}{8}$ in. in diameter, or upon a trunnion. If the pawl is placed upon a trunnion, the pawl is to be secured by a bolt or rivet not less than $\frac{1}{2}$ in. The brake pawl and brake shaft are to be connected by a rigid metal connection.

Brake Wheel

The brake wheel shall be made of malleable iron, wrought iron or steel, and may be flat or dished, not less

than 15 in. in diameter, and is to be fastened to the brake shaft with a square fit in the hub; the taper to be nominally 2 in. in 12 in. The proper clearance provides for not less than 4 in. around the rim of the wheel and other clearances specified call for not less than 4 in. from a vertical plane drawn parallel with the end of the car and passing through the inside face of the knuckle, the coupler and knuckle to be in closed position with the coupler horn against the buffer block or end sill when this measurement is taken.

Location of Brake Shaft

Box and Other House Cars.—On the end of the car, to the left of and not less than 17 in., nor more than 22 in. from the center.

Hopper Cars, High Side Gondolas with Fixed Ends, Low Side Gondolas with Fixed Ends and Low Side Hopper Cars.—To the left of and not more than 22 in. from the center.

Drop End Low Side Gondolas, Drop End High Side Gondolas, All Tank Cars, Caboose Cars Without Platforms.—On the end of the car to the left of and not more than 22 in. from the center.

Flat Cars.—On the end of the car to the left of the center, or on the side of the car not more than 36 in. from the right hand end thereof.

Caboose Cars with Platforms.—On the platform to the left of the center.

Uncoupling Levers or Lift Bars

Uncoupling levers shall be made of any efficient design and may be single or double, without weld. They are to be located one on each end of the car. When a single lever is used, it shall be placed on the left side of the end of the car. Uncoupling levers shall not be more than 12 in. from the side of the car. Center lift arms to be not less than 7 in. long. The center of the eye at the end of the center lift arm shall extend not more than $3\frac{1}{2}$ in. beyond the center of the eye of the uncoupling pin in the coupler when the coupler is against the buffer block or end sill. The handles of uncoupling levers shall extend below the bottom of the end sill not less than 4 in. If the handles are not constructed so as to provide for this, the minimum clearance which must be provided is 2 in. around the handle. The minimum drop for uncoupling levers shall be 12 in. and the maximum 15 in. The distance from the rail to the handle of rocking or push down type levers shall be not less than 18 in. from the top of the rail when the lock block has released the knuckle. Provision shall be made to prevent the inside arm from flying up in case of breakage by having a suitable stop provided. All uncoupling levers for the different classes of cars are of the same kind and dimensions, except those for tank cars without end sills. On these cars the minimum length shall be 42 in. measured from the center line of the end of the car to the handle of the lever.

Sill Steps

Four sill steps shall be provided of wrought iron or steel, without weld. The minimum cross sectional area must be $\frac{1}{2}$ in. by $1\frac{1}{2}$ in. or equivalent, with a minimum clear depth of not less than 8 in. and tread not less than 10 in. If the steps exceed 21 in. in depth, they must be provided with an additional tread. Sill steps are to be fastened with not less than $\frac{1}{2}$ in. bolts with the nuts outside (where possible) and riveted over, or not less than $\frac{1}{2}$ in. rivets. Sill steps are to be located one near each end on each side of the car, not more than 18 in. from the end of the car to the center of the tread of the sill step. The outside edge of the tread shall be not more than 4 in. inside of the face of the side of the car and the tread not more than 24 in. from the top of the rail.

The foregoing rules in regard to sill steps apply to all classes of cars except tank cars without side sills and tank cars with short side sills and end platforms. On such cars one step must be located near each end on each side under the side hand holds.

There are other classes of cars not covered by the above instructions, namely, tank cars without end sills, where the sill steps are to be located one near each end of each side flush with the outside edge of the running board, as near the end of the car as practicable. If these steps exceed 18 in. in depth, they shall be made with an additional tread and be laterally braced.

Two side door steps must be provided on caboose cars without platforms, the minimum length being 5 ft. and the minimum width 6 in., minimum thickness of tread $1\frac{1}{2}$ in.; minimum height of back stop 3 in. and the maximum height from the top of the rail to the top of the tread 24 in. The steps must be located one under each side door and shall be applied and supported by two iron brackets having a minimum cross-sectional area $\frac{7}{8}$ in. by 3 in. or equivalent, each of which shall be securely fastened to the car by not less than two $\frac{3}{4}$ in. bolts.

Caboose Platform Steps

Caboose platform steps of safe and suitable box design shall be located at each corner of all caboose cars with platforms. The lower tread of the step shall be not more than 24 in. above the top of the rail.

Ladders

Ladders are to be made of iron, steel or wood, not less than $\frac{5}{8}$ in. diameter if of wrought iron or steel. Wooden treads are to be not less than $1\frac{1}{2}$ in. by 2 in. of hard wood. Ladder treads may act as hand holds. Ladders and treads must be secured by not less than $\frac{1}{2}$ in. bolts with the nut outside (where possible), riveted over, or with $\frac{1}{2}$ in. rivets. If wooden treads are gained into stiles, $\frac{3}{8}$ in. bolts may be used. The proper clear length of treads is not less than 16 in. on sides of cars and 14 in. on ends of cars. There are exceptions in the case of tank cars without side sills and tank cars with short side sills and end platforms. Ladder treads on such cars shall be not less than 10 in. and shall have not less than 2 in. clearance. When ladders are not equipped with stiles, or with stiles extending less than 2 in. from the face of the car, they shall be equipped so that the bottom tread on the inside end is fitted with foot guards not less than 2 in. high. Ladder treads shall be spaced not more than 19 in. apart. A variation of 2 in. is allowed from the top tread to the bottom tread of the side ladder. The distance allowed from the top tread of the sill step to the bottom tread of side ladders is not more than 21 in. on box and other house cars, the top treads of ladders to be arranged not less than 12 in. or more than 18 in. from the roof at the eaves. The top treads of ladders on coal cars are to be arranged so that they are not more than 4 in. from the top of the car. End ladders are to be spaced to coincide with the treads of side ladders, 2 in. variation being allowed. When the construction of the car will not permit the application of the tread of the end ladder to coincide with the bottom tread of the side ladder, the bottom tread of the end ladder must coincide with the second tread from the bottom of the side ladder. Ladders on different classes of cars shall be located as follows:

Box and Other House Cars, Hopper Cars, High Side Gondolas with Fixed Ends.—Not more than 8 in. from the right hand end of the face of the car, or not more than 8 in. from the left hand side of the end of the car.

Drop End High Side Gondolas.—Side ladders must be located the same as on box and other house cars (no end ladders being required).

Two ladders are necessary on tank cars without side sills

and tank cars with short side sills and end platforms, when such cars have continuous running boards and four ladders on cars having side running boards, if so located as to make ladders necessary. Two ladders on cars with continuous running boards are to be located, one at the right hand end of each side. Ladders on cars with side running boards are to be located one at each end of each running board. One ladder at each end is required on caboose cars with platforms, but the dimensions are not specified. Four ladders are required on caboose cars without platforms, the same as box and other house cars.

The variation allowable in the location for ladders on caboose cars without platforms is as follows: If the caboose has side doors, side ladders shall be located not more than 8 in. from the doors.

The following classes of cars do not require ladders: fixed end low side gondolas, drop end low side gondolas, flat cars, tank cars with side platforms and tank cars without end sills (if these tank cars have high running boards, making ladders necessary, the sill steps must meet ladder requirements).

CONFERENCE RULINGS.

Automobile Cars with Swinging End Doors.—These cars may come under the head of cars of special construction, and the end ladders may be placed as nearly as possible to the designated location.

Ladders.—Spacing of Ladder Treads. The spacing of top ladder treads shall be taken from the eave of the roof at the side of the car, whether a latitudinal running board is used or not.

Ladders and handholes need not be applied to swinging side doors of gondola and ballast cars. Ladders shall be placed on such cars as prescribed for high-side gondola and hopper cars, with the sill step under the ladder, or as near under the ladder as the car construction will permit. The ends and sides of cars are to be equipped with handholds in the same manner as flat cars.

Horizontal End Handholds

Handholds shall be made not less than $\frac{5}{8}$ in. in diameter from wrought iron or steel, without weld. The proper clear length is not less than 16 in., but there are exceptions where it is impossible to use 16 in., and 14 in. may be used. The proper clearance is not less than 2 in. Eight handholds or more are required on certain classes of cars (four on each end) and four on other classes (two on each end).

The following classes of cars require eight horizontal end hand holds: Box and other house cars, hopper cars, high side gondolas with fixed ends, low side gondolas with fixed ends and low side hopper cars.

These end hand holds on the above named classes of cars are to be located four on each end, two of which must be not less than 24 in. or more than 30 in. above the center line of the coupler, where the car permits, except where the ladder tread acts as a hand hold.

There are cars so constructed as not to permit location of hand holds as above specified, namely, some fixed end and drop end low side gondolas and low side hopper cars; these hand holds are to be placed not more than eight inches from the side of the car. The other four end hand holds are to be located on the face of the end sills, not more than 16 in. from the side of the car, projecting outward or downward.

Upon the following classes of cars there can be but four horizontal end hand holds, namely, drop end high side gondolas, drop end low side gondolas, flat cars, tank cars with side platforms, tank cars without side sills, tank cars with short side sills and end platforms, and caboose cars with platforms. The other classes of cars equipped with but four horizontal end hand holds are tank cars without end

sills. The hand holds on these cars shall be located on the running board, one near each side on each end of the car, or on the end of the tank not more than 30 in. above the center line of the coupler, not more than 2 in. back of the edge of the running board. If located on the running board these handholds must project outward or downward.

The horizontal end hand holds shall be located on caboose cars with platforms as follows: One near each side on each end of the car on the face of the platform end sill. The clearance of the outer end of the hand hold shall be not more than 16 in. from the end of the platform end sill. An additional horizontal end hand hold is to be provided for cars with platform end sills 6 in. or more in width, measured from the end post or siding and extending entirely across the end of the car. The proper length of these additional end hand holds is not less than 24 in., and they must be located near the center of the car, not less than 30 in. nor more than 60 in. above the platform end sill, fastened securely with not less than $\frac{1}{2}$ -in. bolts with nuts outside (if possible) riveted over or with not less than $\frac{1}{2}$ -in. rivets. They shall be located on caboose cars without end platforms, in the same relative positions as specified for box and other house cars.

Tank head hand holds are required on tank cars with side platforms. Tank cars without side sills and tank cars with short side sills and end platforms. Two hand holds are specified but are not necessary if the safety railing runs around the ends of the tank. They are to be of $\frac{5}{8}$ in. in diameter, made of wrought iron or steel with not less than 2 in. clearance. They are to be located and fastened one across each head of the tank not less than 30 in. nor more than 60 in. above the platform or the platform on the running board. They must be securely fastened, not less than 6 in. from the outer diameter of the tank.

Vertical End Hand Holds

End hand holds (vertical) shall be provided on cars with platform end sills (described heretofore) being two in number, not less than $\frac{5}{8}$ in. in diameter with the tread not less than 18 in. without weld. The proper clearance is 2 in. and they shall be located opposite the ladders not more than 8 in. from the side of the car and not less than 24 in. or more than 30 in. above the center line of the coupler measured from the bottom end of the hand hold and secured by not less than $\frac{1}{2}$ in. bolts with nuts outside (if possible) riveted over, or $\frac{1}{2}$ in. rivets.

CONFERENCE RULING.

The law makes no distinction between passenger and freight cars, and hand holds must, therefore, be placed on the ends of passenger cars and cabooses.

Horizontal Side Handholds

Side hand holds (horizontal) shall be not less than $\frac{5}{8}$ in. in diameter of wrought iron or steel without weld. Four are required. The proper length and clearance of these side hand holds are as follows: The tread must not be less than 16 in. long with a clearance of 8 in. from the end of the car and must be not more than 30 in. nor less than 24 in. above the center line of the coupler where the car will permit.

The following classes of cars are so constructed as not to permit the location of side hand holds as above specified: some fixed end and drop end low side gondolas and low side hopper cars. Side hand holds are to be securely fastened with not less than $\frac{1}{2}$ -in. bolts and nuts outside (if possible), riveted over or with not less than $\frac{1}{2}$ -in. rivets. Ladder treads may act as hand holds. The location of horizontal side hand holds is not the same on all classes of cars, the exceptions being: flat cars, tank cars with side platforms, tank cars without side sills and tank cars with

short side sills and end platforms. On the above classes of cars they are to be located not more than 12 in. from the end of the car, one near each end, on the face of each side sill. The four horizontal side hand holds on tank cars without end sills are to be located one near each end on each side of the car on the running board over the sill step. They are to be placed on the running board, not more than 2 in. back from the outside edge, projecting outward or downward. When these hand holds are more than 18 in. from the end of the car, an additional hand hold must be placed near each end on each side not more than 30 in. above the center line of the coupler and the clearance of the outer end of the hand hold shall be not more than 12 in. from the end of the car.

Side hand holds shall be applied on caboose cars with platforms, one located near each end on each side of the car, curving downward toward the center of the car from a point not less than 30 in. above the platform to a point not more than 8 in. from the bottom of the car. The top end of the hand hold shall not be more than 8 in. from the outside face of the end sheathing. They must have the following length and clearance: minimum clear length, 38 in., and minimum clearance, 2 in.

Horizontal side hand holds shall be located on caboose cars without platforms as follows: one near each end on each side of the car, not less than 24 in. nor more than 30 in. above the center line of the coupler. The clearance of the outer end of the hand hold shall not be more than 8 in. from the end of the car.

Vertical Side Handholds

These hand holds are used on all classes of tank cars if equipped with safety railings, and there shall be four located one over each sill step, secured to the tank or tank band.

CONFERENCE RULINGS.

Ladders and hand holds need not be applied to swinging side doors of gondola and ballast cars. A side vertical hand hold shall be placed on the corner post of such cars, as nearly as possible over the sill step.

Vertical side hand holds on ballast cars must be applied to the outside face of the corner post, i. e., the faces of same which are parallel to the sides of the car.

Side Door Handholds

Caboose cars without platforms require these hand holds. They shall be four in number, two curved and two straight, located as follows: one curved hand hold from a point at the side of each door opposite the ladder not less than 36 in. above the bottom of the car curving away from the door downward to a point not more than 6 in. above the bottom of the car.

One vertical hand hold at the ladder side of each door from a point not less than 36 in. above the bottom of the car to a point not more than 6 in. above the level of the bottom of the door. They must be not less than $\frac{5}{8}$ in. in diameter of wrought iron or steel, with a minimum clearance of 2 in., securely fastened with not less than $\frac{1}{2}$ -in. bolts with nuts outside (if possible) riveted over or with not less than $\frac{1}{2}$ -in. rivets.

Platform Hand Holds

Caboose cars with platforms require these hand holds, four in number, one right angle hand hold located on each side of each end extending horizontally from the door post to the corner of the car at the approximate height of the platform rail, then downward to within 12 in. of the bottom of the car. They must be not less than $\frac{5}{8}$ in. in diameter of wrought iron or steel, with 2 in. minimum clearance preferably $2\frac{1}{2}$ in. They are to be securely fastened with bolts, screws or rivets.

TEST RACK FOR INSTRUCTING AIR BRAKE REPAIRMEN

BY N. J. CLINE

Air Brake Foreman, Pittsburgh & Lake Erie

A novel and ingenious test rack installed in the air-brake instruction car of the Pittsburgh & Lake Erie is shown in the illustrations. This test rack is used for instructing air brake repairmen in the method of testing a car on the repair track for defects in the air brake equipment.

A 10-in. freight brake equipment stands vertically against the wall, with suitable pipe connections and gages to indicate resulting pressures and their changes. Two triple valves, one known to be in good condition and the other known to be in bad condition, or at least a condition that should receive attention, are also connected. The same is true of the pressure retaining valves installed on the top of the air cylinder, one of them being known as a good valve and the other as one needing attention.

To the left of the brake apparatus is a device for testing

The Air Brake Testing Device Installed in the Instruction Car

brakes on single cars, which is permanently installed as a part of this rack, but is, in detail, exactly like that used by the repairmen on the repair track.

The repairmen are brought into the car in classes, and each man is asked to test out this car equipment, locate any defects, if they exist, and indicate what should be done to overcome them. Brake cylinder leakage can be varied, and either the good or bad triple valve or pressure retaining valve can be cut into the equipment.

The code of tests used with this rack is that for freight brake triple valves, which is as follows:

The tests are to be made with 80 to 90 lb. pressure in the supply line and with the single-car test apparatus.

Test for Testing Device.—Before coupling the testing device to the brake pipe hose, close cocks 1 and 2 and open the

cock in the supply pipe. There should be no escape of air from the coupling at the end of the test device.

Coupling Device to Car.—Connect the coupling A to the brake pipe hose at one end of the car; to the other end on the opposite end of the car couple on a dummy coupling, which should be provided for this purpose. Open both angle cocks, then open cock 1 and charge the brake pipe and the auxiliary reservoir to 70 lb.

Brake Pipe Leakage Test.—Close cock 1, open cock 4, reducing the brake pipe pressure to 60 lb., then close cock 4.

Observe the pressure on the brake pipe gage. Leakage in the brake pipe will be indicated by a drop in pressure, which should not exceed 3 lb. in one minute.

Auxiliary Reservoir and Graduating Valve Leakage.—During the brake pipe leakage test, if the triple valve releases the brake, it indicates either a leaky graduating valve or a leak from the auxiliary reservoir or into the brake pipe past cocks 1 and 2.

Application and Release Tests.—Open cock 1 and charge the brake pipe and auxiliary reservoir to 70 lb. Then close cock 1 and move the handle of cock 3 to position No. 1, reducing the brake pipe pressure to 60 lb. The brake should apply before the brake pipe pressure is reduced to 60 lb. Failure of the brake to apply indicates that the triple valve should be removed for further investigation on the triple valve test rack.

Release Test.—If the brake applies, as specified in the

Device for Testing Air Brakes on Single Cars

Application Test, and brake pipe pressure is at 60 lb., open cock 2. The brake should release in one minute. Failure of the brake to release in the time specified indicates that the triple valve should be removed for further investigation on the triple valve test rack.

Service Stability Test.—Charge the brake pipe and the auxiliary reservoir to 70 lb., then close cock 1. Move the handle of cock 3 to position No. 2, reducing the brake pipe pressure 20 lb. This test should not produce an emergency application of the brake. If an emergency application is obtained by this test, it indicates that this triple valve should be removed for further investigation on the triple valve test rack.

Emergency Test.—Charge the brake pipe and auxiliary reservoir to 70 lb., then close cock 1. Move the handle of cock 3 to position No. 3, reducing the brake pipe pressure to 20 lb. This test should produce an emergency application. If an emergency application is not obtained, it would indicate that this triple valve should be removed for further investigation on the triple valve test rack.

It has been found that instruction by means of this rack has resulted in a far better understanding on the part of the repairmen as to the purpose of the tests made on the repair track and the importance of making repaired equipment pass

these tests before the car is released. With the exception of the single-car testing device, all of the apparatus was obtained from stock and required very little special application.

THE DEVELOPMENT OF PULLMAN TRAFFIC

Since the publication of the article in the January issue of the *Railway Mechanical Engineer* dealing with the needs of the railroads for additional passenger equipment, more data has become available which throws some light on the relative development of traffic carried in railroad and in Pullman passenger cars during the last 15 years and of the increase in the number of Pullman cars which has been made to keep pace with the growth of sleeping and passenger car traffic. In the absence of this information the discussion in the article referred to was confined to equipment of railroad ownership only.

During the ten years ending on July 31, 1915, the number of passengers carried in Pullman equipment increased from 14,969,219 to 21,489,301, or 44 per cent. During the same period the number of cars of all classes owned by the Pullman Company increased from 4,138 to 7,303, or 76½ per cent, but the performance of these cars as measured by car miles showed a proportionately smaller increase of 57 per cent. The number of car miles during the year ending July 31, 1905, was 444,986,296, while for 1915 it was 700,480,779.

At the close of the fiscal year ending July 31, 1919, there were 7,622 Pullman cars of all classes which during the year had carried a total of 33,103,307 passengers and had made 734,031,856 miles. An increase in the number of passengers carried during the four years since July 31, 1915, of 54 per cent has been handled with an increase in the number of cars of 4.4 per cent and in the number of car miles run during the year of slightly less than 5 per cent.

It is unfortunate that there is no record of the number of passenger miles made by travelers in Pullman cars. To determine what the actual traffic increase has been, involves a knowledge of the average miles per passenger trip as well as a knowledge of a number of passengers carried. The best data available on this point are the average receipts per passenger as reported by the Pullman Company. During the seven years from 1911 to 1917, inclusive, the average receipts per berth passenger were \$2.47, with a minimum yearly average of \$2.43 and a maximum of \$2.53. The average receipts per seat passenger were 62 cents for the entire period with a minimum yearly average of 60 cents and a maximum of 63 cents. An estimate of the actual mileage per passenger on the basis of these figures would be complicated by the fact that the average receipts per berth passenger are a weighted average of the rates for uppers, lowers, staterooms and compartments. The uniformity of the proportion of passengers for each of the two classes of Pullman cars and of the average receipts per passenger during the period mentioned seems to justify the conclusion that there was little change in the average miles traveled per passenger during the normal years preceding the war, and that the number of passengers carried may be considered approximately proportional to the number of passenger miles in each year.

It is evident that during the ten years prior to July 31, 1915, there was an increase in the number of Pullman cars greater than the increase in traffic seemed to demand. This is explained by the fact that during this period the construction of steel sleeping cars was developed to a practical point and coincident with the large increase in the number of steel passenger cars of railroad ownership a large number of steel Pullmans were built. These replaced the older wood equipment on many roads, particularly the large eastern roads, but the wood equipment was not actually retired from serv-

ice. The number of cars in service in 1915, therefore, indicates an actual surplus of available equipment, part of which, however, could not be considered available for universal service. This is indicated by the fact that while the number of Pullman passengers per car per year was 3,620 in 1905, it had dropped to 2,940 in 1915. Likewise, the miles per car per year had decreased from 107,600 in 1905 to 96,000 in 1915.

Developments during the last four years, however, have materially changed this situation. With an increase in the number of passengers carried in Pullman cars of 54 per cent, there has been an increase in the number of cars of but little more than 4 per cent. It is true that this has been accompanied by almost no increase in the number of miles per car per year, each car making but 96,400 miles during the year ending July 31, 1919, as compared with 96,000 during the fiscal year 1915. There has, however, been an increase in the number of passengers per car per year from 2,940 to 4,340. This represents a 17 per cent increase in the number of passengers per car per year as compared with 1905, and such data as is available indicates that the ratio for none of the years prior to 1915 varied much from that of 1905. That this increase in service was effected without a material increase in the miles per car clearly reflects the results of the Railroad Administration's policy of filling sleeping cars, uppers and lowers alike.

There are two reasons which make difficult any attempt to arrive at a close estimate of the additional amount of sleeping and parlor car equipment required to meet the needs of the present and immediate future on the basis of past developments: first, the abnormal increase in the number of cars built during the decade prior to 1915, and second, the possibility of much greater utilization of the equipment than was ever developed during the pre-war years. Much of the wood equipment which has long been in use has rendered invaluable service during the war in the movement of troops. The gradual extension of the use of steel equipment, however, probably will considerably exceed the actual need for new cars, and it is inevitable that the surplus wood equipment must be of rapidly decreasing usefulness under normal conditions. It is also probable that with the return of the railroads to private operation the full effect of the lesson in efficient utilization of sleeping car equipment will not be retained by the public and there will be a demand for some choice of accommodations, which has been denied the traveler during the past two years. An increase in the number of cars sufficient to reduce the number of Pullman passengers per car to 4,000 on the basis of the business handled in 1919 alone would require about 700 additional cars, without considering the question of retirements, while to retain this ratio with an increase in traffic during the next few years proportional to the average increase which took place during the decade prior to 1915 would require almost 1,000 more.

This cannot be considered a close estimate, but it certainly may be considered as indicative of the fact that a large number of Pullman sleeping and parlor cars will be needed during the next few years to take care of the demand of the traveling public for a return of some measure of the choice of accommodations enjoyed before the war and to meet the inevitable growth in the passenger traffic of American railroads.

SPAIN HAS TOO MUCH COAL.—Spain, in common with most European countries, has a coal problem, but its situation is diametrically opposite to that of its neighbors: that is, it has a supply greater than the demand. Piled up at the heads and in the coal ports of Asturias lies a stock estimated at from 750,000 to 1,000,000 metric tons (metric ton equals 2,204.6 lb.), and the problem of the moment is how to dispose of this surplus.—*N. Y. Tribune*.

PAINT PIPE LINES IN A CUBAN CAR SHOP

Unique Device for Mixing and Spraying Used with Great Success by the United Railways of Havana

BY J. P. RISQUE*

CLAIMS for new high records in production being generally accepted with certain reservations, the statement that box cars are being painted in eight minutes will be received with interest. A further claim for painting 40 coal cars complete in 3½ hours would probably neither add nor detract from the reader's faith in the first statement. But if he were informed that these records had been maintained for over two years in a section of Latin-America in which he had long believed railroading, in the modern sense of the word, was an unknown art he would attach incredibility to the report. The fact is, however, that the United Railways

of the tired workman and his hand-stirring paddle. The third point in the combination is the construction of the spray or paint gun, which differs sufficiently from stock varieties to make it noticeable.

The mechanical movement provided is solely for the purpose of operating the churns in the mixing tanks, power being derived from a two-horsepower electric motor driving a horizontal shaft through a flywheel. The shaft, mounted on suitable hangers and running in oil boxes fastened thereto, carries a bevel gear on its end. This gear drives its mate and revolves the vertical propeller shaft, which, anchored in a bearing near its top, seats in a collar in the bottom of the mixing tank—in this case an ordinary so-called "one-time" oil drum. A two-blade propeller is fixed near the base of the shaft and runs as close to the bottom of the tank as is practicable without scraping. The blades are pitched to force the agitation upward, and ¾-in. holes in the blades add to their mixing effect. The propeller blades are made from sheet iron and the relation of the motor driven shaft to the flywheel and proportions of gears, have been calcu-

The Paint Gun is Simple But Effective

of Havana have maintained this schedule at their Luyanó shops for the period of time mentioned.

The home-made paint mixing and distributing apparatus described in this article was originated and installed by Ben F. Elliott, master car builder of the aforementioned lines, and is doing efficient and regular business for the company every working day of the year. Coupled with the fact that its successful operation is not particularly enhanced by the temperaments of the operators to be found in these parts, most of whom would—and frequently do—rely on the brush on the slightest provocation, the record can be truthfully said to be phenomenal. Constructed of such miscellaneous and second-hand material as is generally procurable in a large car plant, it is unique in design and simple in operation.

The machine's general arrangement is well set forth in the photograph which accompanies this description. It will be noted that the space occupied by the whole outfit is one which does not conflict in the least with the conduct of the business of the shop. The installation as arranged in reality comprises two paint machines—one for mixing and distributing red paint under air pressure, the other for black, the parts for one end being interchangeable with the other. Three principal features of the device mark it as a combination which is a distinct contribution to the art. The first feature is that of delivering paint ready for use in a spray gun anywhere along a pipe line 600 ft. long or even longer. The second, and perhaps an equally important one, is its function as a paint mixer and the consequent elimination

General View of the Churns and Pressure Tanks

lated to revolve the blades at a speed of from 50 to 60 r. p. m.

Close-fitting removable sheet iron covers for the mixing tank admit of the introduction into the tank of the necessary quantity of paint and oil. When the covers are in place they prevent waste of paint by splashing.

The cylindrical tank below the churn is a receiver into which the mixed paint is allowed to flow by gravity upon the opening of the valve between it and the churn. The receiver is constructed of an old cast-iron flanged pipe and the heads are of wood, bolted into place as shown, with a sheet-iron outside cover.

Compressed air from the shop supply is admitted into the receiver through a reducing valve which cuts the pressure

*Mr. Risque is making a trip through Cuba and Central and South America as an editorial representative of the *Railway Mechanical Engineer*. In future issues we will publish other articles describing the interesting practices which he finds on the railways of Latin America.

down to 60 lb. per sq. in. The valve between the churn and the receiver is closed and the valve from the receiver to the pressure tank opened, and the paint is forced into the latter and out into the pipe line, which can be seen strung along the posts in the photograph. Stations are arranged at convenient intervals along the pipe line, and branch drop pipes bring the paint supply within easy reach of the operator. Painting a whole string of cars along the 600-foot line is then simply a matter of attaching the working hose carrying the paint gun, opening the valve and directing the spray.

As each station is provided with two drop lines with valves, one for a supply of red paint, the other for black, with double valves for air-pipe connections, painting in both colors on trucks and bodies can be carried on simultaneously, and the operation is not confined to one station. In the case of a rush, the number of stations operated is a matter of the supply of paint guns and hose.

Particular attention is directed to the construction of the paint gun, shown in the photograph, which is unique and consists merely of two brass pipes clamped together. The straight pipe carries air at 80-lb. pressure direct from the shop air line. The pipe which is seen to turn into the former carries the combination of paint and air at 20 lb. less pressure than the air pipe, or 60 lb. direct from the pressure tank via the pipe line. It will be realized that, although the paint in the line is under sufficient pressure of air to cause it to rush out of an open valve—in this case, the nozzle of the gun—it is, in reality, comparatively inefficient.

It is only through the energizing influence of its contact with an 80-lb. blast that the mixture assumes the required character to effectively carry it from the gun to the side of the car to be painted. The gun trigger, operated by the

Accumulation of paint in the pipe lines is prevented by "blowing back" through the line. At either end of the 600-ft. run of pipes the two are joined by a tee. The third opening of the tee contains a nipple, with a cut-out valve on it. When this valve is opened, as well as either or both of the valves near the end of both red and black pipe lines, 80-lb. air is blown back through the line—or both lines if desired—

Fig. 1. Arrangement of Mixing Tank and Receiver

past the check valves, also near the end of the lines, and through the opened pressure tank valve into the pressure tank. A special discharge pipe and valve from the pressure tank carry the blown back residue to its original point, the mixing tank. If the paint line happens to become clogged, an incident which has not transpired in two years, provision is made for introducing five gallons of turpentine into the

Fig. 2. Diagram of Paint Distributing System

workman's finger, lifts a plate which bears against the stems of the two valves, one controlling the paint-line supply, the other the 80-lb. air pressure supply. Each valve is raised against the resistance of a small coil spring. As the spring on the straight air pipe valve is purposely somewhat weaker than the spring on the paint-line valve, it is obvious that in pulling the trigger the air line will open first. By this means the 80-lb. air blast is started first. Further pressure on the trigger causes the paint-line valve to yield and commence to admit its contents into the air blast, and the finished mixture rushes out of the end of the gun.

whole system to clean it out. Cleaning out the work hose, which is carried around by the operator and has the gun attached at one end and connects at the pipe line station and air valve at the other, is merely a matter of screwing a cap on the end of the spray nipple and pulling the trigger. The 80-lb. air will quickly blow the 60-lb. air and paint back out of the hose.

As the entire car-painting job is performed by this device without the aid of scaffolding, the saving on this item of cost is obvious. The performance of the machine in painting over 3,000 cars in the last 12 months is characterized by an

absence of the waste of paint which so often accompanies the use of spray painters to a certain degree. No evidence of paint, either spilled or sprayed, is apparent anywhere along the run of tracks where the job is daily handled. The delivery from the tip of the gun is paint thoroughly atomized, its rate of flow does not vary, and the volume of effectual delivery seems to be sufficient to keep the operator on the move.

HANDLING WRECKS AND DERAILMENTS INVOLVING LOADED TANK CARS*

BY W. S. TOPPING

Assistant Chief Inspector, Bureau of Explosives

The loss and damage to life and property, due to the transportation of gasoline during 1918, exceeded many times the loss and damage due to the transportation of the unusually large volume of explosives required to meet war conditions. The average ratio of these losses is about twenty to one. The weight of gasoline shipped under normal conditions is about forty times the weight of explosives of all kinds, and during 1918 the weight of gasoline was about ten times that of explosives. When a comparison is made on the basis of actual weights shipped, during normal years the average transportation losses due to a pound of explosives have been about two times the losses due to a pound of gasoline, but during the year 1918, when abnormal quantities of explosives were shipped the losses due to a pound of gasoline have been two times the losses due to a pound of explosives.

The clearing up of wrecks of tank cars of gasoline and other inflammable liquids involves peculiar risks, owing to the large volume of contents in individual cars and the volatile and inflammable nature of these contents. Owing to the wide diversity of conditions that may exist in such wrecks it is not practicable to draw up regulations which will insure safe handling in all cases. The records of the Bureau of Explosives show instances of ignition of inflammable vapors reported to have taken place at varying distances from the points of leakage. In some instances these distances have been as great as 480 ft., while in others the distances, of course, have been materially less.

Gasoline varies in hazard from the wild and highly volatile casing-head gasolines to the ordinary refinery gasoline. Under ordinary atmospheric temperatures the former gives off many times the amount of vapor in a given time as does the latter. In hot weather all gasolines vaporize more rapidly than in cold weather, but even in the coldest weather gasoline gives off inflammable vapors in sufficient amount to ignite rapidly.

The vapor of gasoline or other inflammable liquids is much heavier than air and tends to form a layer along the ground and only mixes slowly with the air. The mixing with air is increased by wind. The vapor flows along the ground tending to follow the slope of the ground and settles in low places. It will not drift or flow to any extent against the wind, but may travel a considerable distance with the wind. Owing to variations as to volatility of gasoline, amount of gasoline exposed, temperature, contour of ground and direction of wind, it is impossible to fix any definite limit at which the hazard of ignition ceases.

In handling wrecks involving tank cars of gasoline, leaks should be stopped if possible, or the contents of the car transferred. While gasoline is actually escaping all lights and fires should be kept at a distance, this distance being much greater on the leeward side than on the windward. Any necessary lights should be kept in elevated positions. The passage of trains on adjoining tracks or the near approach

of the wreck crane is unsafe, until the leakage can be controlled and the gasoline which has already escaped can be drained away and the saturated area covered with a layer of earth or cold cinders. Even after this is done sufficient time should be allowed to permit the evaporation of any loose liquid, and the diffusion of the vapors, so that they are no longer present in dangerous amount.

When the gasoline is escaping in large quantity, the situation is extremely dangerous and the first steps taken should be to police the location; to cause the removal or prevent the approach of all lights or fires other than closed electric lights; to keep all unauthorized people away. Next, steps should be taken to control the escape of gasoline, if possible, and if not, to dispose of the gasoline which has escaped, so that it will no longer be hazardous. This is generally best done by draining into holes dug in the ground, and then when the liquid has drained away, filling back the loose earth. Care should be taken to avoid permitting large amounts of gasoline to flow into sewers or water courses, as in this way the hazard may be carried long distances from the original point of trouble. After this the usual steps may be taken, using the precautions of keeping lights from the immediate neighborhood of the tank car and if possible bringing the wreck crane up from the windward side.

The precautions suggested will inevitably cause delay in the removal of wrecks, and opening the line; but there is no possible way of safely handling such wrecks while tank cars are leaking gasoline copiously, or gasoline which has already escaped in quantity is still uncared for.

The following general rules will serve as a guide for the majority of cases:

1. Post guards and keep all spectators away.
2. Locate all leaks and stop them if possible, using only electric flashlights or electric hand lanterns when lights are necessary. If open flame lights must be used keep them elevated as much as possible.
3. Dig holes and trenches to bury exposed and leaking gasoline that cannot be transferred promptly to tight containers.
4. Allow reasonable time after stoppage of leaks and burial of gasoline for vapors to escape from the wreck and vicinity.
5. Keep steam crane fire to windward as much as possible and not less than 500 ft. away until completion of work to this point.
6. First move to safety the least injured cars to avoid starting new leaks during handling by crane. When leaks are to be expected in handling, empty the car first either by transfer of contents to other car or container, or by drainage to a hole or trench in the ground for burial.
7. Do not allow trains to pass on adjoining tracks, especially on same or lower level, as long as gasoline is leaking or exposed in quantity. When allowed to pass keep fire doors and ash pan slides closed and draught shut off.
8. The placing of leaking tank cars for repairs in close proximity to shops where fires or naked lights are maintained must be avoided.

SPECIAL PRECAUTIONS FOR CASINGHEAD GASOLINE

The foregoing refers particularly to ordinary refinery gasoline and other inflammable liquids of low flash point, but should not be taken to include casinghead gasoline, either blended or unblended. Such cars, under the I. C. C. Regulations, are required to show special placards on two sides of the dome and on the dome cover, reading as follows: "Caution. Avoid Accidents. Do not remove this dome cover while gas pressure exists in tank. Keep lighted lanterns away."

In handling situations involving such cars, the first procedure is to release very carefully any accumulated interior

*From a paper read before the sixth annual meeting of the Railway Fire Protection Association, held at Chicago, November 18, 19 and 20, 1919.

gas pressure. This should be done by raising the safety valve stem by engaging the end of the metal rod in the eyelet in the top of the valve stem and prying downward against the outer edge of the top of the spring case. Before doing this the tank should be carefully jacked into normal position, or so nearly as to bring the safety valve above the level of the liquid, other wise the liquid instead of the gas will be forced out. Not until the gas pressure has been relieved can arrangements be undertaken with safety to begin the transfer.

If the wrecked tank is not broken or leaking the contents can be transferred by air pressure. This is best accomplished by using a special dome cover with two openings through which pipes are tightly fitted. One of these pipes extends a few inches inside the dome and is used for the air pressure feed; the other passes to the lowest part of the tank and acts as a discharge. If a special dome cover is not

AIR PRESS FOR STRAIGHTENING STEEL SHEETS

BY NORMAN McLEOD

The reclamation of distorted steel parts of cars, particularly the bent sheets of steel cars, is a most important feature in economical car repair work and is being given considerable attention by car repairmen. The air press shown in the drawing is a development brought about by the need of an efficient means of straightening bent steel sheets.

Similar devices have been used, but the press shown has been very successful and a number of them have been built for use in various railroad repair shops.

The framing of this air press is built up of steel channels and angles, firmly braced with gusset plates and steel lattice work, and is supported on a concrete foundation. The bedplate of the press is of cast iron and is 8 ft. 6 in. long by 6

Construction of Air Press for Straightening Steel Sheets

available and a machine shop is located in the vicinity of the wreck the dome cover of the car can be prepared as described above in a short time.

Highly volatile products such as casinghead gasoline cannot be transferred in the usual way by an ordinary vacuum pump. As soon as such a pump creates a partial vacuum the vapor from the liquid fills it and for this reason only vapor will come through. A pump can be used, if connected so that the liquid will flow from the tank to the pump by gravity. Before connecting the pump with the bottom outlet relieve all pressure through the safety valve, and then remove the dome cover and carefully verify the setting of the outlet valve stem.

If it is necessary to bury the liquid dig trenches deep enough to keep all of the liquid well below the surface of the ground.

ft. wide. It is 5 1/2 in. thick and rests on four 6-in. I-beams, making a most ample and rigid bed for any part of a car that may require straightening.

The air cylinder used in this design is 30 in. inside diameter, with a piston mounted on a 3 1/2-in. piston rod, to the end of which is attached the ram or hammer used in straightening a distorted piece. The cylinder is secured to the top cross members of the press frame by four bolts extending upward between the channels. A three-way valve with suitable piping provides for the admission of air to either side of the piston and for the exhaust of the air to the atmosphere.

The space between the side frames is 10 ft. 6 in. and the head room above the bedplate is 7 ft. 9 in., providing ample room for the operators and permitting the use of a sledge if necessary.

NOVEL CHUCK ARRANGEMENT FOR HOLDING DRIVING BOX

BY GEORGE BARNSTRICKER

One method of taking up the side play on driving boxes is to recess the face of the box on a boring mill and pour on molten brass, which is later machined to the desired thickness. In recessing the side of the box it is usually

Chuck Set at 30 deg. Holds Driving Box While Holes are Drilled in Hub Face

cut under in order to hold the brass in place after it has cooled off. It was found in actual practice, however, that this form of attachment was not sufficient, and a series of 32 holes were drilled around the face of the box at an angle of 30 degrees. These holes need not be of any exact size, but $\frac{5}{8}$ -in. holes by $\frac{5}{8}$ in. deep will be found to give satisfaction and insure the brass hub liner remaining in place.

For the purpose of drilling this series of holes in the

driving box face at an angle of 30 deg., the arrangement shown in the illustration will be found a material aid. Two pieces of $\frac{3}{8}$ -in. by $2\frac{1}{2}$ -in. iron are bent to an angle of 30 degrees, and bolted to the base of the drill press, where the driving box drilling work is usually done. An ordinary lathe chuck of large enough capacity to take the largest driving box, as shown, is now mounted on the two pieces of iron and a boss underneath the chuck holds it in place, but does not prevent its rotation. In actual practice, the driving box is mounted on the chuck and clamped as shown in the illustration. The 32 holes are then drilled in the face of the box at a constant angle of 30 degrees by simply revolving the chuck after each hole has been drilled.

JIG FOR MILLING BEADING TOOLS

BY C. W. SCHANE

Instructor of Apprentices, Erie Railroad

The beading of locomotive flues requires careful and accurate work to secure smooth, tight beads so that there will be no leakage and little tendency for honeycomb to form and stop the flues. To do accurate work in beading over the ends of the flues it is necessary to have properly milled bead-

The Beading Tool Miller and the Jig

ing tools. A jig for use in making such tools is shown in the illustration. This jig is made to screw into the index head of the milling machine and when the beading tool is being cut, is adjusted to the proper position to produce the required shape of the tool.

In the drawing the beading tool *A* is shown in outline. A small dog or stop *B* permits the exact duplication of adjustment of the tool by means of the projection or pin *C* on the dog. To adjust a tool in the jig for the milling operation a tool is inserted through the rectangular hole in the top of the jig, with the shank of the tool resting in the adjustable support *D*. The dog *B* is then thrown into place at the tool secured in the desired position by the set screws *E*.

The use of this jig has not only produced beading tools of greater accuracy than it was possible to make by ordinary hand methods, but it has reduced the cost of manufacture from 60 cents to 8 cents each, a saving of 52 cents on each tool.

A ROUNDHOUSE CRANE

BY A. P. SHARP

A jib crane for use in roundhouse work was described on page 205 of the April, 1919, issue of the *Railway Mechanical Engineer*. This crane, as first designed and built, facilitated repair work in the roundhouse, but it was found that the friction which developed at the pivots was so great that it seriously interfered with the operation of the crane. To overcome this trouble, those cranes which had already been built were equipped with roller bearings, greatly increasing their utility. The service obtained from these cranes led to a further improvement, and the new design is shown in the accompanying drawing.

In the present type the jib boom was made of an 8-in.

necessary to provide for the greater range and for the roller bearings. These cranes installed at alternate posts in the roundhouse will increase the capacity of the house for repair work and will soon return the cost of construction.

PIECE WORK—PRO AND CON.—That the hourly wage basis of payment of wages has not produced as good or satisfactory results to either party as some of the special piece work or premium plans that were previously in vogue, is being more or less generally conceded. A careful canvass made recently by the New York Sun among manufacturers to determine the working out on production of enforced shorter hours and increased wages confirmed the belief of economists that its results are not as beneficial as expected. The theory has been that the worker can produce better goods if allowed to work fewer hours a day than his energy is capable of, providing he received increased compensation for the fewer hours, but the great fault of the scheme is that it does not take into consideration the mental attitude of the individual, and where all are on an equal basis and the sloth receives the same pay as the industrious worker, the latter loses his ambition and allows himself to fall to the level of the slower and lazier partner at his work. In the end the ambitious worker is the loser in following this false precept. Progress cannot be made by retarding production and production cannot be increased by slowing down the individual worker. A far better standard is found in a wage system depending not on a fixed scale for the class of

Details and Installation of the Roundhouse Crane

18-lb I-beam instead of a 6-in. 17.25-lb. I-beam as in the original design, a single vertical 12-in. 20.5-lb. channel instead of two 6-in. 8-lb. channels, and the brace is formed of two 6-in. 12.25-lb. channels instead of one. As in the original design, the trolley travels along the I-beam, but the length of this boom, and consequently the range of the crane, has been increased considerably, making it possible to handle more parts at various stages of roundhouse repair work without the necessity of moving the locomotive to come within range of the crane boom.

The castings and other fittings are substantially the same as in the first design, only such changes being made as were

work done so much as in the amount of work produced, which makes the laborer worthy of his hire and puts the individual strictly on his own feet. It is interesting to note that in a recent wage decision the arbitrator denied the demands for the abolishing of piece work. All this would tend to indicate that the turning point has been reached and that a realization that the wages labor receives must be made out of the work labor produces, will bring recognition of the fact that increased and scientific production and payment for same under an individual system, which would give the greatest award to the greatest producer, must go hand in hand.—*Proceedings of the Car Foremen's Association of Chicago.*

THE OLD WAY AND THE NEW; A CAR SHOP STORY*

Autocratic Management Proved a Failure, But An Entire Change of Policy Brought the Desired Results

BY THEODORE RUDOLF

THE first year of our part in the world war had just come to a close when Sidney Stevens stepped from the train in a small Southern town. Endowed with youth, strength, good looks and an active mind, but of a roving disposition, he could never stay long in one place, but drifted about as his fancy dictated. Never having learned a trade fully or having acquired more than a superficial school education, his ambitious mind could not take root in the general occupations open to him. Raised on a farm, an orphan without family ties, he had run off in his fifteenth year to follow the lure of the wide world and had worked his way in numerous callings.

An inborn love for mechanics had kept him for the most part engaged in mechanical work, but having had no training, he could never attain any higher degree to satisfy his ambition, and soon would quit, dissatisfied. Drifting into the war industries, he had worked in several munitions and other factories, but the automatic, soul-killing sameness of his daily tasks there irked his independent spirit to distraction. Earning much more money than his simple habits required, and without any friends of more refined tastes, he would squander it in reckless fits of riotous living, which would only leave him with a greater feeling of dissatisfaction with himself and the world in general. After one of these wild sprees, disgust with it all took him so forcibly that he quit his job and boarded a train south, with the intention of putting as much space between himself and his former haunts as possible.

Awaking one beautiful Southern morning in the train, the country and this little town took his fancy and he decided to terminate his travels on the spot. Aimlessly drifting out from the depot, he noticed the railroad shops nearby, and his love for all that was mechanical tempted him at once to look them over and led him directly into the car shops. His keen, observing mind soon found much of interest. Watching the men here doing carpenter work, there drilling holes in steel beams, others welding truck bolsters or riveting plates, he was quickly struck with the many-sided operations in this work, which would surely leave much to a man's individual creative mind and ingenuity. On inquiry he learned from the men that at the present time help was so badly needed that almost anyone who could swing a hammer would get a job, without regard to previous experience. They advised him to see the foreman of the car department or the general foreman about it, and pointed out the latter to him, who happened to be standing nearby. Sidney at once followed the advice, and soon had his paper and check number, showing that he was employed as an inexperienced car repairer.

Having secured a boarding place, he returned in his overalls, ready for work, and, approaching the foreman of the car department, tendered his paper and reported ready for duty. The foreman, a gruff looking, elderly man, hardly gave him a look, took the paper and walked off, as if he had some important business elsewhere. Sidney waited in the office, and during the next hour the foreman passed by him several times without paying the slightest attention to him. Not knowing what to make of this, Sidney asked one of the men working nearby how he could get started on work.

"How did you happen to be hired?" asked the man.

"Why," answered Sidney, "I asked the general foreman for a job and he hired me and sent me here."

"Well," laughed the man, "that is just where you rubbed the boss against the grain. You see, our boss is a good old man all right and would not hurt a cat, but he has a chronic grudge against himself and all the world, and he's so jealous of his little authority that he's always afraid some one above him is meddling and stepping on his toes. If you'd asked him first for a job he would have sent you to the general foreman for him to hire you, and you would be O.K. with him. Now you'll have to be patient until he softens up again, and I'll tell you what'll happen. You just stay right there and look as if you don't care how long you stay; your time goes on the payroll just the same. First thing the boss will bounce down on you and give you a long lecture about the G. F. and everybody else trying to interfere in his business, and give you to understand that it's a pity for the company that they let them do it, since he himself is the only one that knows anything about the car business, but is not given a chance to show it, and nobody appreciates what a fine car shop foreman he is and how hard he works, and so on. Then, when you are well soaked with all this valuable information about himself, he'll put you to work with one of the men and pay no more attention to you, except that he'll tell some of us fellows that the general foreman has again shipped him another greenhorn that doesn't know a bolt from a 20-penny nail. But don't let that or anything else that seems strange around here worry you. As long as you're hired you're on, just so you do something to look busy."

It soon turned out exactly as the man had predicted, and after being thoroughly inundated with the foreman's troubles he was put to work as partner to an old-timer—a ruddy, rough-looking Southern cracker named Ben Simmons. On short acquaintance Ben proved to be an honest, whole-souled, good companion, who knew his business thoroughly. Good-natured, but with little education or refinement and having spent the greater part of his life in car shops, he had the pride and enthusiasm of his trade that is bred by ignorance of all other callings. Soon he had taught Sidney the tricks of the trade and felt proud of his willing and quick-learning pupil, so that together they turned out work in excess of the other men, and took commendable pride in the fact.

Sidney's many-sided experience soon showed him that there was nothing extraordinary for one of his bright and observing mind in his new calling, even if the foreman and other men tried to convince him that it would take years and years to learn all they claimed to know about it. Often he would try to get some more information about different phases of their work from the foreman, but only received scant replies, given in such a sarcastic way that he desisted and tried the assistant foreman. This man, he soon noticed, was willing enough to give him information, but, like the rest of the officials, seemed to be always afraid to be caught by one higher in rank and lay himself open to the suspicion of knowing too much.

When talking to Ben about this, he laughed and told him not to pay any attention to fellows that thought more of their job than their work any time.

"Don't you never," said Ben, "look for any satisfaction for what you do if any of them can grab it away. When we used to work piece work times were lots more satisfactory

*Entered in the *Railway Mechanical Engineer's* prize story contest which closes on April 1.

'than this, because then your pay check would show whether you were doing something or not. A man had to produce the goods to get anything then. Now any old clodhopper can get in here and soon gets the same wages as we old-timers get, when half of them ain't worth 15 cents a day. Just look at those two fellows over there, working their second day on a pair of draft timbers, the same as we got out in four hours yesterday. But what did we get for making such time? The boss sneered about it, saying that we might have used better timber, when he himself sent us the stuff here to make them. And there he stands, talking with those fellows now for a half hour about some philosophy or other that nobody understands, but all listen and the work just waits till he gets done. When I go to him and ask him to rush us some material we need badly, he'll tell me I am always meddling and interfering in the yard. I'll tell you this is the worst place for asking any questions of anybody, because everybody is scared his answer might be held against him by some one higher up, so you see everybody pussy-footing about the other fellow trying to find out things without having to ask questions."

Sidney, listening to these wise counselings, had a slight feeling of disgust at the hypocrisy of the whole works.

Suddenly his attention was attracted by seeing a young girl crossing the shop track nearby, and at the same time he noticed an empty box car silently coming down the same

He Noticed an Empty Box Car Coming Silently Down the Tracks

track, unnoticed by the girl. In a flash he realized that a car with a broken coupler had patted from the switching train and, rolling down the slight incline, had almost reached the unsuspecting girl. Like a shot he jumped, picked her up unceremoniously and deposited her on safe ground. In her surprise the girl struck out and cut a long gash across his forehead with the edge of her handbag, but did not utter a sound. There they stood now, staring at one another—Sidney speechless with embarrassment at having dared to pick up and rough-handle this wonder of womanhood. Small and shapely, a pretty head within a glory of gold-tinted hair

and a pair of eyes that seemed to search his soul, she appeared to him, with his limited knowledge of refined womanhood, the very embodiment of an angel from heaven.

Now the shadow of the passing car fell on her and, turning about, she quickly realized what this man had done for her. She turned pale at the thought of the fate she had just escaped and, turning again to thank her rescuer, she looked into a face so comical with smears of blood, dirt and embarrassment that she broke out into a silvery laugh. Quickly recovering herself, she thanked him for what he had done in such an open-hearted way that Sidney quickly found his poise again. He waived aside all thanks, explaining how the car happened to be loose.

"It's that old fool of a foreman's fault," he said. "He is

She Suddenly Appeared In Front of Him on the Street

directing the switching and should have watched out for this car."

"No," said the young woman, "it was my fault for trusting so much to the blue flag, laying there now under the car, and not keeping a watchful eye on all tracks, as my dad., who happens to be that 'old fool of a foreman,' has taught me."

With that she laughed her silvery laugh again and was gone before Sidney recovered himself.

Returning to his work, he was glad that no one seemed to have seen his encounter, but he was quiet and like one stunned. Never in all his life had a woman affected him like this. He told himself that it must be because he had never come into close contact with any real lady before, but at the same time he knew that he had, without a second's notice, fallen hopelessly in love with Ellen Goodell, his foreman's daughter.

He did not see her again until two weeks later, when she suddenly appeared in front of him in the street and stopped him with outstretched hand and a hearty greeting. Obviously admiring his gentlemanly looks in his street clothes, she soon put him at ease with her merry talk, and before he knew how it had happened he had accepted her invitation to call on her at her home. There he learned that she had lost her mother and was her father's only companion and housekeeper.

Her father paid no attention to him, merely saying a gruff "Good evening" when he passed through the room, while

Ellen told Sidney not to pay any attention to this; that her father was a dear old bear with all his grumpiness.

Both being honest and open-hearted, Sidney and Ellen soon exchanged experiences and confidences like old friends, but Sidney could not overcome the feeling that this lovely girl, judging from her talk, belonged to a different sphere socially, even if his democratic spirit would never admit that about her father. Yet when he studied her father's ways and those of the other foremen about the shops he could not but see that they tried to surround themselves with a spirit of social superiority that was greatly distasteful to his democratic nature.

Meantime the war advanced, conditions all about changed continually, the men grew restive and nervous, being harassed continually by their union leaders, the advancing cost of living, continued calls for war relief contributions and war bonds. Argument and gossip filled up their time and production lagged more and more. The Railroad Administration, needing cars badly, tried in every way, from stirring the men's patriotism to bringing pressure on them through their foremen, to increase the output, without great results. Many inexperienced men were put to work, the foremen grew harsher and the men more nervous. Cursing and ugly brawls became more common every day.

Sidney, in his sincere desire to do right, worked harder than ever, but only earned sneers from the men and a contemptible smile from his superiors for trying to outdo the rest of the gang. Small controversies with members of the supervising force, when he tried obstinately to uphold what he thought right, only made more enemies for him. The gang foreman who checked his work was an old employee, who prided himself on his great knowledge and on his unimpeachable honesty towards the company in the smallest details. In checking a car for Sidney he questioned the weight and size given by him for a certain iron on the car, and launched into an argument that included the foreman, Sidney, his partner Ben, and two laborers.

Sidney, getting tired of it all, suddenly asked the gang foreman where all his great honesty towards the company came in when the possible difference in the weight of the iron would amount to not more than two cents, while here between the six of them they had already wasted over two dollars' worth of the company's time and had accomplished nothing.

Incidents of this sort being of daily occurrence, Sidney grew more and more dissatisfied with his surroundings. His friendship with Ellen had grown meanwhile into a deep and adoring love on his side, and Ellen herself felt more deeply for him than she would admit to herself.

There seemed to be always some barrier between them which kept them from going out in public together or to mingle in the same sets socially. He saw her alone only at her home, and she would often try then to induce him to give up his present work and take what Sidney called "a white shirt and collar" job. He treated these attempts of Ellen's lightly, but could not overcome a slight feeling of unpleasantness over these trials.

One day, after an exceptionally unpleasant argument with his foreman, who tried to impress him with his superiority when Sidney knew himself to be in the right, he carried his shop troubles into his conversation with Ellen. An argument resulted, which grew to fever heat when Sidney denounced her father's ways and actions, Ellen taking her father's side uncompromisingly. Forgetting all caution, she claimed that her father and she stood so high above an ordinary car knocker that they would lower themselves by yielding an argument to him and that he had better try to get into some more gentlemanly position or else let her alone. In a rage Sidney grabbed his hat, left without a word, and the next day had abandoned his job and the town. He volun-

teered for the army, was accepted, and before long was at the front in France as a car repairer with the railroad forces, where events did not leave him much time to think over his shop experiences.

Twenty months later, when discharged at last and looking about for work, Sidney was given mileage to his place of recruiting, and so happened to return again to the town of his former labors. Seeing the old place once more awoke many recollections, and almost unconsciously he left the train, to begin where he left off. There was a crowd of people at the depot looking for returning soldier boys, and he was at once hailed by many old acquaintances.

Suddenly his heart stood still as he thought, there in the crowd away back, he saw Ellen Goodell, pale and thin, dressed in black, looking at him in a far-off, strange way. His first impulse was to run and embrace her; he had never forgotten her for a moment in all their time of separation. Noting that she made no move, but stood as if frozen to the spot, the recollection of their parting came over him suddenly, and he turned about and walked off without a sign of recognition.

Calling at the car shops the next day, Sidney found many of his former co-workers and was most cordially received by all, until he ran into his old partner Ben, who received him

There in the Crowd, Away Back, He Saw Ellen Goodell

enthusiastically and urged him at once to come back to work with him, saying that since he was an ex-soldier he was assured of a job.

"Yes," said Sidney, "but what about my old friend Goodell; do you think he will take me back?"

"Well," answered Ben, "the old man died of the 'flu' eight months ago and things have been turned inside out around this yard since then. You'll sure like it here now. There is our new foreman, Mr. Woods; go and jump him right now, get your job and come back and I'll tell you all about it."

Sidney approached the man pointed out, a slight but wiry and alert man, slightly gray and with a pleasant, open face. No sooner had he stated that he was an old member of the force and looking for work than the foreman took his hand, congratulated him on his safe return and told him to go back to his job just as soon as he wished to start again. Then he engaged him in some pleasant conversation about his war experiences, but Sidney noted that whenever one of the men approached with a question or request he would stop at once, attend to the man in a short, precise manner, but with a smile on his face, before going back to his conversation with him. When released, Sidney hurried back to Ben and voiced his surprise at the cordial reception he had received.

"Now you are talking," said Ben, "but, oh, boy, you have not half found out yet all the change in this old place. You remember how we used to peg along here with poor equip-

ment and tools, short material to work with, no encouragement from the bosses, petty jealousies among the men and union squabbles. Well, it kept on that way from bad to worse, with production falling off more and more, old man Goodell getting more crabby, and the old office fossils more cantankerous all the time, until the master mechanic got peeved, came over and blessed out the whole outfit and looked about to see where more steam was needed. First thing he sent over a young woman as clerk in the office. Now, wouldn't that jar you—a woman in this car shop? We sure didn't know what to make of it at first, but that girl, with her smile for everybody and prompt and ready answer to every question we had to ask in the office, soon had us all going her way. First thing, the boys marked a line a hundred yards around the office and let every man on the force know that it would not be good for his health to be heard using bad language inside that circle. Soon the boys got so in the habit of minding their tongues that you hardly ever hear them cuss anywhere now. Only that old fossil in the office gets a fit sometimes when that girl goes to work and changes things about, but that don't worry her any. Now they can put their hands on any record there in a minute, while before they always had to hunt all over to find anything.

"Next thing old man Goodell came down with the 'flu' and died, after a long hard struggle. Our men and their wives went there and did all they could, and Miss Ellen, who seemed not to like their coming at first, later realized what good friends our people were to her, and she has stuck to them ever since. She makes her living now working in an office downtown, since the old man didn't leave her anything, and mighty sad and lonely she looks, too.

"Next comes this here new foreman walking in on us one fine morning, and the old man in the office gives up to a new man who used to be in business and runs the whole office like a business, too. Well, every blessed morning since he came the foreman has found time to go all over the shop yard and give a pleasant 'Good morning' and cheery word to everyone of us, but his eye goes flying around and he sees everything that's going on. If anyone has a request he listens and gives a prompt answer, and I often see him do three things at one and the same time, like talking to the big boss, answering questions for his men, signing papers, all with the same smile, and yet nothing escapes his eye that's going on around the yard. He may not know as much about car repairing as old man Goodell did, but then he'll accept a suggestion from us old-timers anyway and even ask our opinion of how some things should be done. He is on to every man here and how to handle him—to get the most work out of him, which seems to be his pet study.

"See those two Italians over there? They used to be about the slowest team on this ranch. Some time ago they had a heavy repair job on a coal car and didn't make any headway at all with it at first. What do you think he does? Cuss them? Not on your life. He just gives them a little talk on the coal shortage misery every day as he goes by, until those fellows got so interested that they felt they made a lot of poor women and kids up north suffer just so much longer for want of that old car to move coal. First thing they worked like blazes to get rid of the car, and they were proud as peacocks when she rolled out of the yard. That's the way he'll get us all interested in whatever we do; he always has something to tell you that stirs you up somehow. He'll talk about tools or metal or merchandise or anything, and he has those coach workers so interested they lose sleep sometimes thinking over their jobs. He got them impressed by degrees with how much damage a poor job of theirs can do to a crowd of passengers, so they always feel as if they are responsible for the lives of the people that travel in their cars.

"Besides making us look differently at the work we are

doing, all the boys are in the habit now of going to him with our personal troubles and there's nothing so small that he won't have a kind word of advice for. If it's anything about our time or some writing to be done, he sends them to his office and the clerks there are always willing and ready to listen and do what they can. The boss never wants to hear anybody say about anything, 'I haven't got time.' You can go to his office with a little scratch on your hand or any kind of hurt and they'll drop everything else and clean and bandage you. But let any fellow try to tell him a tale about some one—he'll make him prove it or eat it, and he'll fight at the drop of a hat if he sees any crooked things going on.

"We did have some underhand agitators around here that tried to stir up a little trouble, but they quit and left the country as soon as the boys caught on to their works. It didn't seem healthy around here for them. Now you know why we all like to come to work here in the morning."

Sidney soon became familiar with the new conditions and worked with a new enthusiasm, seeing his dreams of working conditions coming more true all about him. He received another surprise at the first meeting of their local union

Sidney Simply Picked Her Up and Held Her to His Heart

which he attended. Formerly the men, in their unofficial debates after the business meeting, talked about nothing but grievances, sport, drink and so forth; now the conversation was almost entirely about their work. With wonder he was told that there was a monthly production contest going on between their shop and the nearest one on the system. It was altogether unofficial, but the clerks in both offices were gladly working overtime to supply the data, which were figured out somewhat after the old piecemeal schedule. Interest in the outcome was intense, resulting in increased production at both shops. The foremen on both sides never interfered, he was told, except to see that only good work left the shops.

Sidney's intelligent and honest work was quickly recognized by the new foreman, who often stopped to talk to him briefly, feeling him out on different topics, until one day he asked Sidney to a social gathering to be held at his home that evening. He explained that this was an altogether informal gathering of men and women interested in their line of work and said that these little socials often gave them all much help by giving them an opportunity to talk over

matters that they had not time enough for during working hours.

Sidney welcomed the diversion. Ben's recital of Ellen's troubles had touched him deeply; he loved her still, but was afraid to meet her, not knowing how she would receive him and still yearning to go to her to comfort and protect her.

At the foreman's house he was received like an old friend by Mrs. Woods and her daughter. He found a number of the shopmen and some of their wives, so that he felt quite at home at once.

Still other guests were arriving when Miss Woods asked him to come with her to meet her dearest friend, who was helping to prepare some refreshments for them all. Following her into another room he noticed a young woman with her back turned to him. When he approached she turned about, and then Sidney found himself looking straight into the eyes of Ellen Goodell. His heart jumped at the message those eyes held for him, when Ellen held out both hands to him and in a low voice said, "Sidney, can you forgive me? I have since found out what happiness it gives to serve, and that in service we are all equals."

Stunned by the suddenness of it all, Sidney simply picked

And How this Ever Revived Them and Spurred Them to Renewed Effort

her up and held her to his heart. After an interval of blissful forgetfulness of all his surroundings, he said, "Child, I'll never leave you again, but our squabble was too serious; it can only be patched up by a preacher, and he'll have to act pretty soon at that." To this Ellen readily consented and sealed the agreement with a kiss.

Guiltily looking around, they found themselves all alone in the room. Joining the company again they were greeted with congratulations and laughter.

"Well, said Mr. Woods, "talk about a rapid fire, you two sure get the prize, from the looks on your faces. Here my wife and girl framed this meeting carefully, to get you two together again by degrees, and you take the whole works by storm at the first shot. You must have learned that in the war."

After the pleasant excitement over this happy solution of the lovers' quarrel had subsided, Mr. Woods skillfully led Sidney to recite some of his experiences as car repairer at the front in France. As he warmed up to his subject and his recollection of incidents came back, he became eloquent in

his enthusiasm, and the whole assembly was listening in breathless concern to his narrative. He told how many a time they had realized that thousands of lives of their brave boys in the war front had depended on the despatch of a train of munitions or food, and how he and his companions had worked to utter exhaustion to get the damaged rolling stock in condition again. How under gruelling shellfire and unspeakable conditions of filth, mud and hunger, as men standing next to him were blown into eternity; when despair of being able to go on further had turned into abject fear and horror and he had felt ready to lay down right then and give up, their lieutenant, with the eternal cigarette between his smiling lips, would turn up and simply tell them not to forget, that they were only allowed to stay back there in comparative safety and comfort so that they could serve those gallant boys up ahead, who had to get along in a living hell to fulfill their duty, and how this ever revived them and spurred them to renewed effort.

"That was the time," Sidney said, "that I realized fully and forever, that the laborer's real pay is not in his envelope, but in his service to his fellow man."

"There, friends," broke in Mr. Woods, "is the keynote of success for all workers alike. Service to the good of humanity. They say that corporations have no soul, but I say, that from the same point of view the great mass of our unions, supervisory officers and workmen have the same lack of soul and only when all parties concerned will go out to hunt for and recognize the other fellow's soul, will there be real harmony and better times for all.

"I firmly believe that the American workingman has too active a mind and too broad a conception of life, not eventually to find his way out of all the present misconceptions and troubles, into this line of thought. So let us all hope and put forth our individual efforts in the great task of smoothing the path between employer and employee, with the thought of service to mankind ever before us."

A NEW LUBRICANT.—A new fruit containing a large percentage of oil has been discovered in the region of Torreón, Mexico, and is known by the name of chichopoxtle. Experiments show that 25 per cent of its contents consists of oil of great value in industrial pursuits requiring a lubricant of high quality. It is proposed to introduce the cultivation of this fruit on a large scale.—*Railroad Men.*

Railway Bridge at Narva, Esthonia, Destroyed in Campaigns Against Bolsheviki

STANDARD MOTION WORK AIDS VALVE SETTER

Fundamental Valve Gear Dimensions Are Carefully Checked With the Blue Print at West Albany

BY J. McALLISTER

General Foreman, West Albany Shop, New York Central

THE work of setting valves on a heavy repair locomotive is greatly simplified and reduced when the important dimensions of each valve gear part are made to check with the blue print before that part goes to the erecting shop for assembly. This careful checking of dimensions is made necessary by two conditions. First, the builders are not infallible, and occasionally a mistake is found in a practically new locomotive valve gear. For example, the distance between the steam edge of the back port and the center of the link trunnion of a locomotive equipped with a Walschaert gear was recently found to be $\frac{5}{8}$ in. longer on one side than on the other.

The second reason for checking dimensions is that valve

not noted and corrected in the machine shop they will have to be corrected by the valve setter, who does not discover them until all the motion work has been connected up. This involves taking down at least part of the motion work again, and very often results in a delay to the locomotive. Obviously the best way is to check all motion work carefully in the machine shop and, as far as possible, make it correspond exactly with the blue print.

Method of Handling Motion Work

While it is not claimed that any new method of setting valves has been developed at West Albany, the following system of handling motion work through the shops has made

Fig. 1. Gages Used In Checking Valve Gear Dimensions at the West Albany Shops

setters often make slight alterations when squaring a valve, and by the time a locomotive has had three or four general repairs there may be serious differences between the actual valve gear dimensions and those called for by the blue print. As an example of the latter case, the practice of making valve adjustments by upsetting or lengthening the radius bar may be mentioned. This results in a radius bar that does not correspond in length with the link radius and introduces irregularities into the valve motion. Sometimes the distances between pin centers of the combination lever are not in the right proportion, or the lead is not properly equalized by the union link. Perhaps the right-hand valve stem is longer than the left or the valve chamber bushings are too near together.

A valve gear may be completely overhauled and all worn parts renewed, but if the above-mentioned discrepancies are

valve setting a comparatively simple operation which requires only a minimum of time.

All locomotives shopped for classified repairs have the valves and motion work removed and sent to the machine shop. Exact measurements are taken with gage C, Fig. 1, of the distance from the steam edge of the back port to the center of the link trunnion on each side of the locomotive. This distance is marked on valve setting Form No. 1, which is then delivered to the machine shop foreman. The valve chamber bushings are calipered and gaged, using gage B. The bushings must gage properly, and if they do not, new ones are applied and bored out. If found to be out of round and not below the limit of thickness, the bushings are bored.

All parts of the motion work are dismantled and new hardened bushings and pins are applied where necessary. All worn parts are built up by autogenous welding and

machined to the standard size. The radius bars are trammed for length, using standard stationary trammels made to conform to the true radius of the links. If not of the proper length, the radius bars are sent to the blacksmith shop for correction. The combination levers are lined up on a surface table and measured for the proper distances between pin centers. If they are found not according to the blue print, corrections are made. The links are ground to the proper radius. The link blocks are built up by autogenous welding and refitted. Trunnion plates are applied, the holes

The locomotive is now placed on the centers in full gear forward and back. The eccentric crank is trammed for the neutral position, the lead marked and adjustments made in the eccentric rod if necessary. The engine is run over, with the reverse lever hooked up to adjust the cut-off to 25 per cent for passenger locomotives and 30 per cent for freight locomotives. The lead, valve travel and piston cut-off are taken in both forward and back motion. Adjustments are made to equalize the piston cut-off, a greater variation than one-half inch not being permitted. The necessary offsets for crank arm keys is measured.

Valve Setting Form No. 1

being reamed and new bolts fitted. If the trunnion centers do not check with the link centers, new trunnion centers are turned and bushings applied.

The valves are dismantled, the valve stems are ground or renewed as necessary and fitted to the valve crosshead. New packing rings are properly fitted to the bushings. The valves are then assembled and measurements taken from the center of the combination lever pin hole in the valve crosshead to the edge of the back steam ring, using gage A. This distance, plus the length of the radius bar, must equal the meas-

Before removing the crank arms to apply the rods, they must be gaged with the usual form of crank gage supplied for that purpose and readings taken. When reapplied and permanently keyed, the crank arms must check with the readings. Valve setting Forms No. 1 and No. 2, after being filled out, are kept as a permanent record.

As previously indicated, the above method of making motion work repairs and setting valves has worked out well, and the results have amply repaid all additional care and attention given this matter. Locomotives are no longer delayed by mistakes in the valve gear discovered at the last minute; no time is wasted "squaring values" after the locomotive has had a trial run; a good valve gear is assured, which sounds square, has an equalized cut-off and gives a good distribution of steam.

ADJUSTABLE MILLING CUTTERS

There are many places where milling cutters which are adjustable in width can be used to advantage. The ordinary types of adjustable cutters, however, are not satisfactory because the width can only be adjusted slightly less than twice the overhang of the blade. An interesting design of adjustable cutters in use at the Dale street shop of the Great Northern is shown in the illustration below. The cutters are used in pairs. The body of each has one side perpendicular to

Valve Setting Form No. 2

urements marked on Form No. 1, plus the lap of the valve. Parts are delivered to the erecting floors ready for assembling.

Method of Setting Valves

The motion work is assembled on the locomotive, the valves put in and port marks scratched on the valve stems. The reverse lever is placed in the central position and the link blocks lined up or down to get a dead valve on both sides. The combination lever is plumbed. If the work has been done properly the valves will be neutral. The union links are connected up, the locomotives placed on centers and the lead marked on the valve stems. If the lead is not properly equalized, alterations are made in the union link.

Milling Cutters With a Wide Range of Adjustment

the axis, while the other side is cut out at a small angle to it. The key ways are located so that when placed on the arbor the narrow part of one cutter is adjacent to the wide side of the other. By placing rings between the two parts, the width of the cut can be varied by an amount equal to the difference between the length of the longest and the shortest blade. As the total length of the cutters which are in operation remains the same at all times, there is no change in the torque on the arbor and no tendency to chatter. This arrangement has been found useful for cutting out shoes and wedges, cross-head shoes and similar parts.

RAILROADS FAIL BADLY IN TRAINING SHOPMEN

Mechanical Department of Railroad Administration
Compiles Statistics as to Number of Apprentices

ALMOST fifteen years ago George M. Basford, then editor of the *American Engineer and Railroad Journal*, made his memorable address before the American Railway Master Mechanics' Association, in which he pointed out the vital necessity on the part of the railroads of giving immediate attention to the selection, preparation and training of men for railroad service. The *American Engineer and Railroad Journal* and its successor, the *Railway Mechanical Engineer*, have consistently emphasized Mr. Basford's recommendations, in season and out of season, for all these years.

What has been the net result, so far as the mechanical departments of our railroads are concerned? We are ashamed to have to admit that very little has been accomplished. Whether it be because Mr. Basford was too far ahead of his time, whether because of lack of ability on the part of Mr. Basford's followers and the technical press in presenting the matter to the railroads, whether it be a lack of vision and executive ability on the part of the railroad managers, or whether it be a combination of all of these things, the results in the railroad field have been truly disappointing. Men in other industries have been quicker to adopt Mr. Basford's suggestions and, directly or indirectly, his suggestions have had a big influence on the development of the National Association of Corporation Schools and the speeding up of apprentice training in the industrial field.

No one has accused the mechanical department of the Railroad Administration of being wildly enthusiastic about the extension of apprentice training. Why should it be? If when the Railroad Administration took over the control of the railroads it had had behind it 10 or 12 years of real apprentice training its task would have been much easier. The railroads had never given the matter any serious attention (except in a few isolated spots); why should it do so? Moreover, the most ardent advocates of the proper selection, preparation and training of employees are not foolish enough to promise immediate results—and immediate results were what the Railroad Administration had to have.

In spite of this, however, Mr. McManamy has compiled complete data as to the number of workmen, helpers and apprentices in each craft on all the roads under federal control. This data is given in full in the accompanying tables. It does not give us any particular pleasure to publish it. We dislike to have to show up a condition which, to say the least, does not reflect any credit upon the railroad mechanical departments of the United States. We pride ourselves on leading the world with our wonderful railroads and our efficient methods. It is too bad that we do not compare more favorably with foreign roads when it comes to the selection, preparation and training of employees. It is strange that we have so little appreciation of the importance of the human factor in our railroad operations.

The figures as to the number of apprentices of course tell only part of the story, bad as it is. If as concrete a picture could be presented of the methods of instruction of apprentices on the different roads, the shock would be still greater. A few—a very few—roads have gone at the problem in a big way, but the great majority have just played with the task and have hardly touched the edges of the job.

Organized labor has the reputation of keeping down the percentage of apprentices. Has it? It seems more than passing strange that those sections of the country where shop labor was so highly organized in pre-war days should show

up so well in comparison with other sections. It surely looks as if the railroad shop managements should be held to their accountability in restricting the number of apprentices. If the figures as to machinist apprentices do not bother you, run your eyes along the line to the other crafts. Do not hurriedly jump over the carmen.

But why comment further? The figures tell the dismal story plainly enough. If the Interstate Commerce Commission or some other governmental agency should step in and take a hand in the matter by ordering improvements to be made there would be an awful howl—but what are the railroads doing to make good?

In June, 1905, Mr. Basford closed his address with these words: "Are we a nation so enveloped in a cloak of progress that we cannot see the future?" Since 1905 hundreds of our big industrial companies have met this challenge by inaugurating modern up-to-date methods for training their men. Ought we not today ask this question: "Are the railroads of the United States so sound asleep as to the importance of training and developing the human factor that they will fail to make good in the future?"

* * *

Assume for a moment that the railroads generally did awaken to their full responsibilities and really did inaugurate modern up-to-date apprentice systems, would that be sufficient? No! To make these measures fully effective—and we, of course, assume that they would be accompanied by steps to insure the proper selection of boys and young men—it will be necessary to take measures to study critically the disposition, ability and performance of each individual in the organization so that the men may be assigned to those tasks for which they are best fitted and in order that promotions may be made intelligently and in the best interests of the organization as a whole.

We subject the most ordinary materials that we use on railroads to all sorts of tests, even resorting to the compound microscope and to micro-photographs. But what about the most vital factor in railroad or industrial organization—the human factor? Why is John Smith assigned to lathe work? Is it because he is better fitted for that particular work than for other tasks, or is it purely accidental? Why was Bill Jones made gang boss or foreman? Is it because he had been subjected to critical study over an extended period, or is it because he happened to be in favor, or particularly prominent, at the time the appointment was made?

If the wrong man is promoted how much damage is done? In the ranks Bill Jones was an individual. As a foreman his inefficiency may be multiplied by the number of men under his direction. Moreover, other men, realizing that he is a misfit, feel that merit is not recognized and lose any ambition to strive to so perfect themselves as to be available for promotion. They reason that the chances of being hit by promotion by "the hit and miss" method of selection are about the same as being hit by lightning. Because promotions are not made by scientific, accurate means and because no standards of measurement are set, they lose interest or, if they do believe in lightning rods, take such peculiar measures as they think will give the best results in attracting the attention of that peculiar and uncertain element.

It is too bad, for the solution of these difficulties is so simple and easy, and so well worth while, if we would only awaken to the seriousness of the situation.

TABLE II—MECHANICS, HELPERS AND APPRENTICES IN ALL DEPARTMENTS, BY CRAFTS—ALLEGHENY REGION—Continued

Table with columns for Railroad, Machinists, Boilermakers, Blacksmiths, Sheet Metal Workers, Electrical Workers, Carmen, Moulders, Other Mechanics, and Grand Totals. Rows list various railroads like Coal & Coke, Grand Rapids & Indiana, etc.

TABLE III—MECHANICS, HELPERS AND APPRENTICES IN ALL DEPARTMENTS, BY CRAFTS—POCAHONTAS REGION.

Table with columns for Chesapeake & Ohio, Norfolk & Western, and Virginian. Rows list these railroads and their respective counts for various departments.

TABLE IV—MECHANICS, HELPERS, AND APPRENTICES IN ALL DEPARTMENTS, BY CRAFTS. SOUTHERN REGION.

Large table with columns for Alabama & Vicksburg, Alabama Great Southern, Atlanta & West Point, etc. Rows list numerous railroads in the Southern region and their personnel counts.

SLIDING HEAD DRILLING MACHINE

An upright sliding head drilling machine built by the Sibley Machine Company, South Bend, Ind., includes several new features not found in preceding types. The machine as now being built has a swing of 24 in. and the 25-in. vertical adjustment of the head makes it possible to drill work held

Sliding-Head Drilling Machine With the Cast Bearings

in large jigs. Positive geared feeds are provided and both speeds and feeds are selective and have a wide range. To insure strength and rigidity for heavy duty the base of the drill is well ribbed and braced. Increased length of bearings on the head and the arm and substantial table support give added strength and accuracy. A weight to counterbalance the head and the spindle is supported inside the column by a Diamond chain operating over large diameter sheaves. All gears are enclosed to insure the safety of the operator and belt guards can be furnished if desired.

The fitting of all drive shaft bearings with die-cast split bushings made of anti-friction metal is stated to be an ex-

clusive feature of this machine. These bearings are easily interchangeable and their use insures a long life for the bearings. Attention is called to the new geared feed with four changes and a neutral position. The feed changes are obtained by moving a knob conveniently located in the center of the handwheel, in connection with a sliding spline, four feeds being provided for each spindle speed. The initial drive of the feed shaft is from the top cone shaft through spur and spiral gears. This arrangement is very compact so the gears can be completely enclosed and run in an oil bath. The steel worm which meshes with the large worm gear also runs in an oil pocket.

The adjustable automatic stop of new design is quick and positive in action. Hand feed and quick return of the spindle

Four Feed Changes are Obtained Through the Feed Gears and Spline

is effected through the medium of a three-legged spider, at the right of the feed box. Special attention has been given to the oiling of the machine. All bearings are equipped with oil cups, grooves and channels, which insure a proper dis-

tribution of oil to the vital points. All feed gears in the feed case are completely enclosed and run in oil. A positive geared tapping attachment, geared or belted motor drive, round or square table with T-slots and oil pocket, oil pump outfit complete and quarterturn countershaft can be furnished as special equipment with this machine. The total height of the drill is 94 in. and the maximum distance from the spindle to the table and base are $35\frac{1}{2}$ in. and $52\frac{1}{2}$ in., respectively, while the head and the table have a traverse on the column of 25 in. and 13 in., respectively.

GEARED HEAD LATHE

The patented geared head lathe illustrated is manufactured by the Cincinnati Lathe & Tool Company, Cincinnati, Ohio, and is arranged for single-pulley belt drive, directly from a line shaft. The lathe may be arranged for direct motor drive by mounting the motor on the headstock or in the rear of the cabinet leg. In this case the drive is through belting, silent chains or gearing. Variations in speed are obtained in the head, therefore only constant speed motors are required. Twelve mechanical speed changes in geometrical progression are secured on these lathes by means of sliding gears. The movement of the gears is controlled by three shifting levers, and their operation and use is plainly indicated. The levers and gearing are so arranged that they will not lock while operating, and any lever may be shifted without interfering with the others.

The index plates are simple and easily read, so that the

Geared Head Lathe Manufactured by the Cincinnati Lathe & Tool Company

most inexperienced operator will have no trouble in obtaining any speed or feed desired. The spindle may be stopped by the usual control lever on the right of the apron.

The design of this lathe is somewhat similar to the line of lathes manufactured by the Cincinnati Lathe & Tool Company, except that the method of driving the spindle through the gears makes the lathe rather more adaptable to manufacturing work than to tool work. Abundant power is provided to drive the lathes under heavy cuts, and the easy and quick manipulation of operating levers has also been provided for. The latter can be provided with a hexagon turret if desired.

LIMIT SCREW PITCH GAGE

In the past many screw pitch gages have been made with no tolerance and a normal lead only. A new development in these gages which adds to their usefulness is shown in the illustration. As indicated, two additional surfaces are provided on the reverse side, one of which is cut with a lead .002 in. long and the other .002 in. short, thus making a limit gage. When the old style of gage was laid in the thread of a screw it was possible to check the lead on the screw, but in case the lead was not correct, it was impossible to tell how much of an error existed.

Many tool room foremen favor a type of plug gage which unfortunately has the same disadvantages mentioned above and in addition is susceptible to inaccuracies due to wear and is a time consumer in use.

With the new style gage illustrated, if the thread to be

Greenfield Limit Screw Pitch Gage

tested is not normal it can be determined readily whether the thread is longer or shorter than the limit portion of the gage, or whether the error is between these limits. The gages are made for the present to control lead limits of plus

and minus .002 in., which is the most generally used lead limit. Eventually it is intended to supply gages with tolerances of .001, .003 and .004 in. for both long and short lead.

When using the gages it is essential that the work being tested, as well as the gage, is clean in the thread and that the gage is held in the screw in a position parallel to the axis. In testing the thread with this gage the work should be held up to the eye in front of a bright light, so that the resulting error in lead can be detected easily. The gage is manufactured by the Greenfield Tap & Die Corporation, Greenfield, Mass.

MARTIN TOOL HOLDER

The tool holder illustrated, has been designed for use with broken and worn high speed steel drills and tool bits, and is manufactured by the Martin Tool Holder Company, Jackson, Tenn. The body of the holder is made of tool steel, and will last practically indefinitely. The cutting edge of the tool, being made of broken high speed steel drills, reamers, etc., will stand up under heavy cuts, and there is a saving of expensive high speed steel scrap, which would

HIGH POWER MILLING MACHINE

The milling machine, designed for high production, is now recognized as a more or less universal tool, and there has been a steady increase in the range of work that can be performed on it. Great power, rigidity, convenience of operation and adaptability to light or heavy manufacturing or jobbing work is provided for in the new No. 3 plain milling machine recently placed on the market by Joseph T. Ryerson & Son, Chicago. The most striking feature in the design of this machine lies in the application of the helical drive. When this form of drive is used the constant turning power applied to the milling cutter not only insures a better grade of work, but increases the life of the cutter. The objection to helical drive gearing in the past has been the inability to secure a sufficiently wide range of speeds for a commercial machine, but this difficulty has been overcome in the machine illustrated.

Front View of Ryerson-Conradson No. 3 Plain Miller

otherwise be of no value save for the expensive operations of remelting and reforging.

The method of holding and grinding the tool bit is clearly shown in the illustration, and either round or square bits can be utilized. It is claimed that this form of tool holder

Tool Holder Designed for Use With Broken High Speed Steel Drills and Tool Bits

is capable of taking cuts limited only by the power of the machine.

Martin tool holders are made in all standard sizes, and the absence of large bosses or set screws, saves much of the operator's time previously spent in handling, grinding and changing heavy solid tools. The resulting economy is obvious.

The column is a rigid casting, thoroughly ribbed internally and cast integral with the base. The face of the column is extended above the over-arm, thus affording a very thorough support for special fixtures. The heavy type vertical milling attachment with this solid backing is capable of taking as heavy a cut as the main spindle. The knee is heavy and deep, absorbing vibration due to heavy cuts. The bearing surface between the knee and the column is greatly increased by extending the back of the knee up to a point nearly level with the top of the table. The elevating screw telescopes the knee, and is located at its center of gravity to avoid all binding action when raising or lowering. The hand-

wheel controlling longitudinal table travel extends diagonally from the side of the saddle. The spindle is of .60 carbon steel, accurately ground and runs in phosphor bronze bearings, which are adjustable for wear. The base plate is forged integral with the spindle and is arranged with two large keys for driving face mills and arbors. Twelve spindle speeds are available, ranging from 17 to 290 r.p.m. in practically geometrical progression. The driving pulley is of the conical friction clutch type and means are provided to automatically apply a brake to the shaft as soon as the clutch is disengaged.

The feed drive is positive from the primary shaft by means of a chain and sprocket. Eight changes are provided, ranging from .6 in. to 22.3 in. per minute. Each feed screw is provided with a graduated dial reading to thousandths of an inch and readily set back to zero. All feeds are equipped with six trips and the table can be stopped at any desired position along its travel.

The vertical milling attachment illustrated is made in three sizes, and clamped to the column dove-tail, no dependence being placed on the over-arm. The heavy pattern type has the same diameter spindle and the same bronze bearing as the main spindle. The taper hole face plate and driving keys also are the same, permitting as heavy a

cut to be taken as on the horizontal spindle. This is a particularly important feature. The drive is effected by a large aluminum bronze gear, bolted to the face plate of the main spindle and driven by the cross key. In return it engages a steel gear on a horizontal shaft, driving the vertical spindle through a set of bevel gears. This allows the

Vertical Milling Attachment of Semi-Universal Type

spindle to be set at any angle parallel to the face of the column. A draw bolt is furnished.

The longitudinal movement of the table is 35 in., with a cross movement of $14\frac{5}{8}$ in. and vertical movement of 20 in. The machine is driven at a constant pulley speed of 600 r.p.m., requiring a motor of from 5 to $7\frac{1}{2}$ rated horsepower.

MEDIUM SIZED BORING MILLS

With an appreciation of the need of a boring mill to take heavy cuts on medium and small sized work, the Cincinnati Planer Company, Cincinnati, Ohio, has recently added to its line of boring mills a new machine built in 42 in. and 48 in. sizes, one of which is shown in the illustration. These are high production machines, built to take heavy cuts at high speed. They have a capacity of two inches over the rated size, and take 39 in. under the tool holder.

The table is driven by a large, accurately planed bevel gear. The large bevel pinion which meshes into it has a double bearing in the bed, thus insuring smooth motion of the table. Among other advantages may be mentioned the fact that the spindle and track, and also all bearings in the speed box, are oiled by forced lubrication. The bed is reinforced by heavy I-beam ribs and is bored out and bushed for all revolving parts. No pit is necessary for the driving mechanism. All gears in the feed and speed boxes are made of steel, and the enclosed feed boxes are provided with direct reading feeds. Rapid power traverse of the head is provided in each direction, and the traverse handle is adjustable to suit the operator. As a safety feature, the crank handle cannot be engaged when the rapid power traverse is used. Sensitive adjustments are provided for both heads. The

housings are of box type construction and extend to the bottom of the bed. They are held in alinement with the bed by a tongue and groove. All gearing is completely covered and the steel feed racks have teeth cut the entire length.

The travel of the tool bar is 27 in. Eight feeds are provided, ranging from $\frac{1}{40}$ in. to $\frac{1}{2}$ in., and the range of table speeds is from 2.45 to 59.2 for the 42-in. size, and 2.1 to 50.5 for the 48-in. size. A 10-hp. motor is required to drive either of these boring mills, and if direct current is available, a 2 to 1 variable speed motor, not exceeding 500 to 1,000 r. p. m. is recommended. For variable speed motor drive, the cone pulleys are omitted and a single belt drive used instead. The motor is mounted on top of the arch and coupled directly to the driving shaft, as shown in

Cincinnati Boring Mill Built in 42-in. and 48-in. Sizes

the illustration. Boring mills of this type can be equipped with countershaft drive and a belt shifter, if desired. They can also be furnished with a constant speed motor on the arch, in place of the tight and loose pulleys.

Ease of manipulation and the proper placing of all control handles has been constantly kept in mind in the design of these 42-in. and 48-in. boring mills, and all unnecessary steps around the machine have been eliminated.

LAVOIE AIR CHUCK

About four years ago an air chuck was developed in a large manufacturing plant which was producing war material, and was the means of turning out a large production of small lathe work. This air chuck proved so satisfactory in operation that steps were taken to commercialize it, and it is now being manufactured by the Frontier Chuck & Tool Company, Buffalo, N. Y. While this chuck has been manufactured for only about six months, it is by no means a new and untried tool. It is a new departure in air chucks, owing to the fact that the component parts are all embodied in one unit.

The chuck cylinder and piston is an assembled unit,

mounted on a chuck base plate, which is attached to the spindle in the same manner as with an ordinary chuck. This feature greatly simplifies the application. The single unit is of such size as to insure rigidity and strength and because there is but one packing, the usual complications found in this class of equipment are eliminated. It is stated that the lever and wedge which control the action of the jaw embodies a positive clamping action, which is original with the Lavoie chuck. Due to its simplicity, the chuck may be expected to give satisfactory service over a long period of time. The packing used in the Lavoie chuck is of the cup leather type, and is applied to the piston by means of a ring and screws of such size as to insure saving of time on renewals.

The chuck is made in five sizes, varying from 8½ in. to 18 in., the length of the chuck from the spindle end to the face ranging from 6⅞ in. to 5¼ in. Six types of jaws are provided, varying from universal solid manufacturing jaws to combination three-step jaws for general chucking

Air Chuck Manufactured by the Frontier Chuck and Tool Company

work and combination solid or detachable manufacturing jaws. An air box is used in connection with the Lavoie air chuck, and is necessary in order that the air pipe line can revolve with the spindle. The operating valve is a three-way cock, lever operated. One opening connects with the air supply, the second with the cylinder, and the third with the jaws. By the use of this valve only one pipe line is required.

PORTABLE LUBRICATING UNIT

The general design of a compact lubricating unit, manufactured by the Fulflo Pump Company, Blanchester, Ohio, is shown in the illustration. This portable unit was designed to fill the demand for a compact, inexpensive cutting tool lubrication system that could be quickly applied to any machine tool in the shop. Many machine shop tools are not equipped with a pan and pump, because they are used mostly for working on grey iron, but occasionally the machine may be used on malleable iron or steel, in which case a coolant is essential for the best results. In such cases, the portable unit illustrated can be used to good advantage. It may also be used on machines already provided with a coolant system, which for some reason or other is out of order. In this emergency the portable system shown can

be immediately brought into place and production will not be interrupted.

The Fulflo pump illustrated is a complete, self-contained system, requiring nothing but attaching the motor cord to the lamp socket. The total height from the floor is only 14 in., which permits its being rolled under any ordinary lathe, as shown in the illustration. Provision is made for attaching additional splash boards when required. The pump and motor are completely covered, thus affording

Fulflo Portable Lubricating Unit Used with Turret Lathe

ample protection from both liquids and dust. The outfit can be used on grinding machines as well as on lathes, milling machines, drill presses, gear cutters, etc. There is only one moving part in the pump; namely, the impeller, which has no metal contact, and therefore cannot wear out quickly. It is packed with metallic packing which will not cut the shaft. The bearings are well lubricated, and since the shaft is hardened and ground, long, continued service may be expected.

MULTI GRADUATED PRECISION GRINDER

It has been difficult in the past to machine screw thread surfaces with the same accuracy obtained in machining cylindrical, flat or spherical surfaces. On account of this fact, it has been hard to make master thread gages and the machine illustrated was designed for this purpose by the Precision & Thread Grinder Manufacturing Company, Philadelphia, Pa. It can be used in conjunction with any machine tool and is adaptable to a variety of work, particularly thread grinding on lathes. The model C grinder illustrated is a right-hand attachment for use in front of the lathe center. Attention is called to the new style of wheel trueing arm, which is now attached to the base of the grinder in such a way that the thread angle is dressed on the wheel on a plane with the axis of the work centers, thus insuring a perfectly formed thread. This model also has a positioning pin for quickly locating the angle for V. U. S. and Whitworth threads.

The grinding spindles are carried in five precision ball bearings adjustable for radial wear and end thrust play. They are protected from abrasive dust by felt-lined steel

bushings. The spindle housing, carrying these ball bearings is provided with an oil reservoir, insuring continuous lubrication. The style of spindle bearings precludes the possibility of getting out of alinement, as in the case of solid bearings. Vibration and chatter are eliminated by making

automatically keeps it at the proper tension to prevent slipping, and at the same time allows slack enough to prevent loss of power and overheating. The capacity of the machine is limited only by the size of the lathe to which it is attached.

Model C Precision Thread Grinder

the base and spindle housing proportionately massive and of solid construction. The spindle housing fulcrums in a vertical traverse plate and is indexed with graduations for setting to any angular inclination to conform to the helical angle of the thread.

The machines are equipped with individual motors of

COLD SAW CUTTING-OFF MACHINE

A recent development in cold saw machines for cutting off large ingots and heavy forgings, has been made by the Newton Machine Tool Works, Inc., Philadelphia. This cold saw is equipped with a 76-in. diameter inserted tooth saw blade, which has a capacity for cutting 24-in. diameter stock in one cut. The main work table bolted to the machine base is 56 in. long in the direction of the feed of the saw and 48 in. wide. To this table there is bolted a platen 60 in. long by 56 in. wide by 12 in. deep, with suitable T-slots. On this platen there is a clamping block 18 in. wide at the base and 12 in. wide at the top. This block is in line with the top of the main table referred to above. Two V-blocks are fitted to the main work table and one V-block is fitted to the platen. A swivel arch clamp is supplied for each of the V-blocks, and these are so arranged as to hold work 32 in. in diameter.

The drive of the machine is from a belt-connected motor through a solid bronze worm wheel and hardened steel worm fitted with roller thrust bearings. A spur pinion with teeth cut in the solid shaft transmits the power to the spindle driving gear. The feed motion is taken from the drive shaft through gears to the oil-tight feed box in which the change gears are mounted on a sliding sleeve controlled by latch levers in the cover. From this box the motion is transmitted to the saddle feed screw through a feed worm and worm wheel which is positively clutched.

The control of the machine is from the rear. The forward feed is provided with an automatic stop, and the rapid traverse forward and back also has an automatic stop. The feed and rapid traverse mechanism is enclosed with

Powerful Cold Saw Cutting-Off Machine Designed to Use 76-in. Diameter Inserted Tooth Saw

any specified voltage and either direct or alternating current may be used. The power transmission is accomplished by means of an endless belt indicated, which has a three-point contact with both the driving and driven pulleys, and then travels over a compensating two-pulley arrangement, which

curtain covers. Positive safety release is provided for each extreme position of the traverse. The oil and chip pan is cast on the base and drains the lubricant back to the reservoir. A loose chip pan is fitted between the tables for draining to the base oil pan.

Railway Mechanical Engineer

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Subscriptions, including the eight daily editions of the *Railway Age*, published in June, in connection with the annual convention of the American Railroad Association. Section III—Mechanical, payable in advance and postage free: United States, Canada and Mexico, \$2.00 a year; Foreign Countries, \$3.00 a year; Single Copy, 20 cents.

WE GUARANTEE, that of this issue, 12,100 copies were printed; that of these 12,100 copies 11,177 were mailed to regular paid subscribers; 20 were provided for counter and news company sales, 223 were mailed to advertisers, 32 were mailed to employees and correspondents, and 648 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 36,300, an average of 12,100 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. P. C.).

The Paducah, Ky., roundhouse and shops of the Nashville, Chattanooga & St. Louis, which have been idle since the beginning of the war, are to reopen on March 1.

Employees killed on the railroads of the United States, operated by the government, in the month of November, 1919, numbered 231 and employees injured 10,191, as compared with 359 killed and 11,248 injured in November, 1918. These are the totals shown in Bulletin No. 12, issued by the Safety Section, United States Railroad Administration.

Circular 263 of the Southwestern regional director cites a gasoline fire which resulted in a loss of \$8,620, due to the negligence of a car repairer who worked on a leaky tank car with an open flame lantern, in violation of all regulations. The bulletin emphasizes the importance of observing all rules governing the transportation of explosives and other dangerous articles.

The Railroad Administration and the principal railroad companies have adopted the plan which has been reported from time to time as the negotiations have progressed for the financing of the equipment ordered by the Railroad Administration in 1918 by means of individual equipment trusts, payable in 15 annual instalments, with the Guaranty Trust Company of New York as trustee.

An abstract from the Times' Trade Supplement states that the Colombian railways are at present in great need of new rolling stock. In the very near future extensions are to be made, and this will create a demand for locomotives, coaches and freight cars. There will also be a large demand for permanent way materials owing to the reconstruction of large sections of the Colombian railways.

Because of the very disadvantageous rate of exchange, directors of several of the English railroads have issued instructions that no purchases are to be made in America except where it is absolutely impossible to obtain the same products elsewhere. Lines are being drawn more closely day by day against purchases in America by the railways in all European countries, due to the great disparity in the value of money. Furthermore, the railways in every country are making, as never before, every attempt to make purchases within their own frontiers. This will have a serious effect on English business, which relies to such a very great extent on its export business to balance the necessary imports.

New Fuel for French Locomotives

The Paris, Lyons & Mediterranean has decided to adapt 200 of its locomotives to crude oil or Mazout. The modification is expected to be effected at the rate of two engines a day. Reserve tanks will be set up at suitable points on the system to hold between 40 and 100 tons of fuel.

The plant modifications are neither difficult nor costly, being simply a reservoir in place of the coal bunkers, conducting tubes to the burners and refractory bricks in the fire-box.

At an official test held at Bercy on November 25, the locomotive drew a heavy goods train on approximately half the weight of fuel which would have been necessary for the work if coal had been used. There is practically no smoke and it is expected that this fuel will save much labor in the enginehouses.

Investigation of Chilled-Iron Car Wheels

It has been noted for several years that failures of chilled cast iron freight-car wheels occur quite frequently at the foot of long and steep grades. The cause of such failure appears to be the heating of the wheel produced by the prolonged application of the brake-shoes, this rise in temperature causing complicated stresses in the structure of the wheel. The stresses thus produced may be sufficient to cause cracking and failure and in all probability a derailment of the car under which the wheel is placed.

In order to determine the exact temperatures in different portions of the wheel, after prolonged heating of the rim, the Bureau of Standards has instituted a complete investigation of this subject. It is obvious that temperature measurements can not readily be made upon a wheel in service, and considerable ingenuity has been shown in perfecting a laboratory apparatus capable of producing conditions analogous to those met with on the road.

Australia Manufacturing Railway Supplies

Several Australian engineering firms have taken up the manufacture of railway supplies, and the Chief Commissioner for Railways, James Fraser, of New South Wales, has expressed complete satisfaction with the local products. He said that he had been pleased to give preference to Australian

manufactures, and he had not had to pay higher prices than for goods of the same quality from foreign sources. The New South Wales railway administration has been making axles, wheels and tires for both freight and passenger cars in its own shops, and shortly everything required for making a locomotive, with the exception of boiler plates and copper tubing and plates, will be made in Australia, and even the latter will be produced in Australia before long. Mr. Fraser said that he had been promised delivery next March of copper tubes by an Australian manufacturer at a slightly lower figure than that for which he could get copper tubes abroad.

The New Zealand government has placed a contract with an Australian shop for 20 express locomotives. This shop has already turned out over £300,000 worth of work, to the complete satisfaction of the New Zealand railways.

Locomotive Building in Belgium

According to a recent report on the subject of locomotive production in Belgium, says the Railway Gazette, London, there were in that country prior to the war 20 factories in which the construction of railway engines was undertaken. The whole of these were damaged very considerably by the German army and most of the plant removed, one factory being completely destroyed. The work so far undertaken since the cessation of hostilities has been limited to the repair of the buildings and plant, and, as far as has been possible, replacement of the shop equipment. The shortage of engines and the poor condition of those available give scope for immediate activity in this branch of industry, but the shortage of fuel, the difficulty of obtaining raw material, etc., want of capital and the exorbitant demands of the workmen, all stand in the way of progress. The total number of workmen at present employed is 4,542, or about 75 per cent of the number employed in 1913, and these are engaged in repairing locomotives for the State and branch railways. The raw material for a few engines on order in 1914 was hidden and escaped the capacity of the invaders, and the completion of these engines, with a construction of a few others, form today all that the Belgium workshops are able to do in the matter of locomotive production.

Changes in Erie Railroad Organization

On the return of the railroads to private control a radical change will be effected in the official personnel of the Erie. The principal feature of the new plan is the establishment of four regions, each, with one exception, consisting of three or more operating divisions. Each of these regions will be placed in charge of a manager who, reporting to the general manager, will be in practically entire charge of all phases of work done in his particular region. With this in mind each regional manager is to have a regional engineer, a mechanical superintendent, a general freight and passenger agent, a superintendent of transportation, a claim agent, an auditor, an assistant treasurer, a storekeeper and a chief of police. The former divisional organization is to be retained and the superintendents of the several divisions will each report to the manager of the region in which they are included.

The general manager's organization is to consist of a general superintendent of transportation, a general mechanical superintendent, a chief engineer, a general storekeeper and an inspector police.

The regional engineer, regional mechanical superintendent, etc., will each report directly to the regional manager, but in order that their work may be properly co-ordinated they will also report indirectly to their respective officers on the general manager's staff or to the other officers at the head of the railroad organization as the case may be.

The four regions will be known as the New York region, Hornell region, Ohio region and Chicago region.

William Schlafge, formerly general mechanical superintendent with office at Meadville, Pa., has been appointed mechanical manager on the general manager's staff, with headquarters in New York.

The four regional mechanical superintendents are as follows: W. S. Jackson, New York region, Jersey City, N. J.; formerly mechanical superintendent of the Lines East, with office in New York. Charles James, Hornell region, Hornell, N. Y.; formerly mechanical superintendent of the Lines West, Youngstown, Ohio. A. G. Trumbull, Ohio region, Youngstown, Ohio; formerly assistant to the general mechanical superintendent, Meadville, Pa. G. T. Depue, Chicago region, Chicago; formerly shop superintendent at Susquehanna, Pa.

Material Specifications for Tank Cars

The Mechanical Section of the American Railroad Association has recently issued Circular S III-92 giving notice that the suspension of the requirement for boiler plate steel, flange quality, for plates of class III tank cars, as authorized by circular No. S III-67, dated October 10, 1919, is hereby extended to continue in effect until April 1, 1920, only.

The material for all plates of tanks of class III tank cars built after that date must comply with section 2 (a) of the specifications for class III tank cars, 1919 edition, page 21, which reads as follows:

"Material—(a) For cars built after April 1, 1920, all plates for tank and dome shall be of steel complying with the American Society for Testing Materials specifications for boiler plate, flange quality."

The tank car specifications, as revised 1919, effective February 1, 1920, are now ready for distribution, and will be supplied at the following prices to members of the association: 100 copies or more \$15 per 100; 50 copies \$8; less than 50 copies, each 25 cents.

W. H. Woodin Says Railways Need 849,500 Cars

William H. Woodin, president of the American Car & Foundry Company, has made an investigation, as a result of which he estimates that the railroads of the United States will need 849,500 cars during the next three years. It is Mr. Woodin's opinion that while this need, if it is supplied, will run into a tremendous amount of money, the railroads will begin to renew their equipment once the carriers have been returned to private ownership, and that the money will be forthcoming to finance the undertaking. Unless measures to increase the efficiency of the railroads are consummated, he considers that there may be a serious interference with the normal ebb and flow of business. He draws attention to the fact that even now some factories have closed because, due to the car shortage, they cannot get materials.

To make up the present apparent shortage it is asserted 240,000 cars are needed. Replacement for retirement through the next three years will require 234,300 cars, and to take care of increased business it is estimated that 375,200 cars will be needed in the three-year period. The replacement figure is on the basis of an average retirement of 3½ per cent a year and the increased business on 5 per cent a year.

The following table shows the requirements for replacement and increased business during the three years:

	Replacement	To handle increased business
1920.....	73,500	118,500
1921.....	78,000	125,000
1922.....	82,800	131,700

These requirements, Mr. Woodin believes, are not beyond the capacity of the car builders of the country, but it is believed that under the present adverse conditions regarding purchase of steel and other materials it would not be possible to turn out more than 600,000 cars, or some 200,000 a year.

Electrical Workers Strike on St. Paul

Chicago, Milwaukee & St. Paul shopmen employed in the shops at Deer Lodge, Mont., recently engaged in an unauthorized strike because of a desire to force a decision in matters pending before the arbitration board at Washington.

As a direct result of the difficulty practically the whole electrified division of the St. Paul, extending from Harlowton, Mont., to Avery, Idaho, was operated with great difficulty. Federal officers of the road, on hearing of the strike of the shopmen, requested them to await arbitration. However, the shopmen refused, and 48 hours later the electrical sub-station operators on practically the whole electrically-operated division walked out in sympathy with the shopmen. Electrical experts and officers of the electrified division took the places of the sub-station operators as far as possible, and in many places on the division it was found necessary to use steam to maintain service. Director General Hines was immediately notified, and after stating that the sub-station operators' strike was in violation of their contract, issued a 48-hour ultimatum, and the men acceded to his request and returned on February 5. Approximately 300 shopmen and 40 sub-station operators were involved. During the strike some through passengers were detoured over the Northern Pacific.

Reorganization of the Pennsylvania System

The Pennsylvania System has been reorganized for operating purposes after March 1, and has been divided into four regions.

System officers have been grouped under an executive department having attached thereto a transportation department, a traffic department, a financial department, an accounting department, a purchasing department, a real estate department, a legal department, an insurance department, an employees' saving fund department, and a relief and pension department. Samuel Rea will, of course, be president, and reporting directly to him there will be a vice-president in charge of operation, W. W. Atterbury; a vice-president in charge of traffic, George W. Dixon; a vice-president in charge of accounting, A. J. County; a vice-president in charge of real estate, purchases and insurance, M. C. Kennedy; a vice-president in charge of corporate work at Pittsburgh, James J. Turner. There will be two secretaries, one at Philadelphia, Lewis Neilson, and one at Pittsburgh, S. H. Church. In addition there will be a vice-president in charge of personnel, G. L. Peck, who will report to Gen'l. Atterbury.

The combined lines east and west of Pittsburgh have been divided into four sections: The eastern, from New York to Altoona, Pa., and Washington, D. C.; the central, from Altoona to Buffalo, N. Y., Columbus, Ohio, and Mansfield; the northwestern, from Columbus and Mansfield to Chicago; and the southwestern, from Columbus and Cincinnati to St. Louis, Mo. Each of these will be in charge of a regional vice-president. The four regional vice-presidents are Elisha Lee at Philadelphia, R. L. O'Donnel at Pittsburgh, J. G. Rodgers at Chicago, and Benjamin McKeen at St. Louis.

Each regional vice-president will have on his staff a general manager, a general superintendent of transportation, a chief engineer of maintenance of way, a general superin-

tendent of motive power, general superintendents, a traffic manager, a purchasing agent, a real estate agent, and an accountant. On the eastern and central regions there are assistants to the general manager, general superintendents of transportation, etc., commensurate with the amount of business to be handled by the region.

The transportation department, headed by General Atterbury, will consist of a chief of transportation, C. M. Sheaffer, at Philadelphia, with assistants; a chief of motive power, J. T. Wallis, at Philadelphia; a chief mechanical engineer, A. W. Gibbs, at Philadelphia; an engineer of transportation, E. W. Smith, at Philadelphia, and a chief engineer, A. C. Shand, at Philadelphia, with a considerable staff of assistants.

The relations between the central organization and the regional organizations is particularly interesting and constitutes an entirely new departure for the Pennsylvania, although some features of it were inherent in the Harriman system of roads, as this system was being developed at the time of E. H. Harriman's death. It will be remembered that Mr. Harriman had a director of operation for the entire Harriman system. W. W. Atterbury, with the title of vice-president in charge of operation, might well have been designated director of operation. While each regional vice-president is responsible for traffic, maintenance and operation in his territory, General Atterbury's duties consist of coordinating the work of these officers in regard to both operation and maintenance. His supervision will therefore be more comprehensive than a mere setting of system standards. This is true also of the executive vice-presidents in charge of traffic, finance, accounting and purchases. While the regional vice-presidents have on their staff traffic and purchasing officers they can also avail themselves of the vice-presidents at Philadelphia as consulting experts.

The Altoona shops will be in charge of a works manager, P. F. Smith, Jr., with a shop accountant, an assistant chief of motive power (car), an assistant chief of motive power (locomotive), and a motive power accountant. In other words, the Altoona shops will be organized in much the same way as is an industrial manufacturing plant.

The following list gives the names of mechanical department officers their new titles, positions and headquarters.

SYSTEM OFFICERS

Name	Title	Headquarters
J. T. Wallis.....	Chief of motive power.....	Philadelphia (formerly gen. supt. motive power, Altoona)
P. F. Smith, Jr....	Works manager.....	Altoona (formerly gen. supt. motive power, Lines West, Pittsburgh)
J. R. Black.....	Shop accountant.....	Altoona
R. L. Kleine.....	Asst. chief of mot. pwr. (car)...	Altoona (formerly chief car inspector, Altoona)
F. W. Hankins....	Asst. chief mot. pwr. (loco.)...	Altoona (formerly master mechanic, Altoona)
G. M. Ellsworth..	Motive power accountant.....	Altoona
A. W. Gibbs.....	Chief mechanical engineer....	Philadelphia
E. W. Smith.....	Engineer of transportation....	Philadelphia (formerly supt. motive power, Cent. Div., Williamsport)

EASTERN REGION

J. M. Henry.....	General supt. motive power....	Philadelphia (formerly asst. gen. supt. motive power, Altoona)
Eliot Sumner....	Supt. motive power, N. J. div..	New York

RAILROAD CLUB MEETINGS

Club	Next Meeting	Title of Paper	Author	Secretary	Address

SOUTHWESTERN REGION

C. R. Peddle....Purchasing agent.....St. Louis

MEETINGS AND CONVENTIONS

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

AIR-BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 163 Broadway, New York City. Convention May 4-7, Hotel Sherman, Chicago.
AMERICAN RAILROAD ASSOCIATION, SECTION III.—MECHANICAL.—V. R. Hawthorne, 431 South Dearborn St., Chicago. Convention, June 9-16, 1920, Atlantic City, N. J.
AMERICAN RAILROAD MASTER TINNERS' COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.
AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—R. D. Fletcher, Belt Railway, Chicago.
AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 21, 1920, New Monterey Hotel, Asbury Park, N. J.
AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
AMERICAN STEEL TREATERS' SOCIETY.—W. H. Eisenman, 154 E. Erie St., Chicago.
ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.
CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 626 North Pine Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.
CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—Thomas B. Koeneke, secretary, Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—H. J. Smith, D. L. & W., Scranton, Pa.
J. C. Keene, Decatur, Ill.
INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, C. H. & D., Lima, Ohio.
INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. G. Crawford, 542 W. Jackson Blvd., Chicago. Convention, May 24-27, 1920, Hotel Sherman, Chicago, Ill.
INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn.
MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York. Convention May 25-28, Curtis Hotel, Minneapolis, Minn.
MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION OF U. S. AND CANADA.—A. P. Dane, B.&M., Reading, Mass.
NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.
RAILWAY STOREKEEPERS' ASSOCIATION.—J. P. Murphy, Box C, Collinwood, Ohio.
TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

PERSONAL MENTION

GENERAL

C. D. KINNEY, master mechanic on the Boyne City, Gaylord & Alpena, with office at Boyne City, Mich., has been promoted to superintendent of motive power, with the same headquarters. Mr. Kinney was born on August 25, 1876, at Conneaut, Ohio, and attended Conneaut High School. He took employment with the New York, Chicago & St. Louis in November, 1896, as a machinist apprentice, later working as a machinist on that road and on the Southern, the Central of Georgia and the Seaboard Air Line. From November, 1902, to April, 1908, he was general foreman of the Seaboard Air Line at Fernandina, Fla. He

C. D. Kinney

was then general foreman of the Kanawha & Michigan at Middleport, Ohio, and in May, 1910, was appointed master mechanic there. In November, 1912, he went to the Chicago & Alton, as general foreman at Roodhouse, Ill., remaining there until November, 1913, when he became enginehouse foreman of the Baltimore & Ohio at Pittsburgh, Pa., and later at Holloway, Ohio. From November, 1915, to October, 1916, he was master mechanic for the Robert Grace Contracting Company, Pittsburgh, Pa., and then went to the New York, Chicago & St. Louis as machine shop foreman at Conneaut, Ohio. In October, 1919, he became master mechanic of the Boyne City, Gaylord & Alpena at Boyne City, Mich., and in January, 1920, was appointed to his present position of superintendent of motive power.

CHARLES BOND, mechanical engineer of the Erie, with office at Meadville, Pa., has been appointed general foreman of the centralizing plant, succeeding George W. Armstrong, resigned.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

J. E. BROGDEN, whose appointment as superintendent of the Waycross, Ga., shops of the Atlantic Coast Line was announced in the February issue, was born on March 10, 1876, at Sumter, S. C., and attended Clemson Agricultural & Mechanical College from 1893 to 1895. His entire railroad service has been with the Atlantic Coast Line, having entered its employ as a machinist apprentice in 1896. In 1903 he was promoted to the position of roundhouse foreman at Florence, S. C., and was appointed general foreman on April 1, 1904. On April 1, 1906, he was transferred to Savannah, Ga., and about a year later to Montgomery, Ala. On January 1, 1918, he was appointed master mechanic at Montgomery, and on August 1, 1918, was transferred to Waycross, Ga., as master mechanic of the Waycross and Savannah districts.

C. H. CHAMBERS, road foreman of engines on the Atchison, Topeka & Santa Fe, has been appointed assistant air

brake instructor, with jurisdiction over the Western, Arkansas River, Colorado and New Mexico divisions, with headquarters at La Junta, Colo., succeeding M. O. Davis, who has resigned to accept a position with the Westinghouse Air Brake Company at Topeka, Kan.

R. R. HERRICK has been appointed master mechanic of the Detroit, Bay City & Western and the Port Huron Southern at Bay City, Mich.

I. B. IRVIN, general foreman of the Pittsburgh, Shawmut & Northern at Angelica, N. Y., has been appointed master mechanic without change of headquarters, and the position of general foreman has been abolished.

LOUIS METZGER, chief inspector at the Jersey City, N. J., roundhouse of the Erie, has been promoted to the position of roundhouse foreman.

W. N. MITCHELL, formerly master car builder on the Missouri, Kansas & Texas, and who for the past five years has been engaged in government valuation work, has been appointed superintendent of the car department of the Missouri, Kansas & Texas, with headquarters at Denison, Tex.

F. H. MOORE has been appointed assistant master mechanic of the Maritime district of the Canadian National Railways, with headquarters at Moncton, N. B.

ARTHUR L. ROBINSON, assistant to the general superintendent of the Wabash, with headquarters at St. Louis, Mo., has been appointed to a newly created position in which he will supervise the adjustment of controversies between the management and the employees.

GEORGE SEARLES has been appointed master mechanic of the Arizona division of the Atchison, Topeka & Santa Fe, with headquarters at Needles, Cal., succeeding Charles Raitt, assigned to other duties.

J. P. STEWART has been appointed road foreman of engines of the Atchison, Topeka & Santa Fe, with jurisdiction over the Second and Third districts of the New Mexico division, with headquarters at Las Vegas, N. M., succeeding C. H. Chambers.

SHOP AND ENGINEHOUSE

JAMES M. COBLE has been appointed shop superintendent of the Buffalo, Rochester & Pittsburgh at Rikers, Pa., succeeding W. W. Scott, resigned.

OBITUARY

GEORGE LINDSAY, formerly master mechanic of the Evansville, Ind., shops of the Evansville & Terre Haute, died in that city on January 24, aged 69 years.

EDWARD P. RIPLEY, chairman of the board of directors and formerly president of the Atchison, Topeka & Santa Fe, and one of the greatest railroad executives America has produced, died in Santa Barbara, Cal., on February 4, as the result of complications following an operation performed several months ago. Mr. Ripley was born at Dorchester, Mass., on October 30, 1845. He began railway work in 1868 as contracting agent for the Star Union Line at Boston, Mass. From October, 1870, to 1872, he was clerk to the general eastern agent of the Chicago, Burlington & Quincy, and from the latter date to 1875 he was New England agent. He then became general eastern agent, and on June 15, 1878, was made general freight agent. He held the latter position until 1887, when he was appointed traffic manager, and the following year he was promoted to general manager of the Burlington. In August, 1890, he was chosen third vice-president of the Chicago, Milwaukee & St. Paul, which position he held until he became president of the Santa Fe on January 1, 1896.

SUPPLY TRADE NOTES

The Conley Car Company, Pittsburgh, Pa., has changed its name to the Conley Tank Car Company.

E. C. Middleton has been appointed advertising manager of the Colburn Machine Tool Company, Franklin, Pa.

Theodore L. Dodd & Co., Chicago, have been appointed district sales representatives for the Titusville Forge Company, Titusville, Pa.

Samuel M. Vauclain, president of the Baldwin Locomotive Works, Philadelphia, has returned to this country after a brief visit to Europe.

C. E. Bransfield, foreman for the Standard Car Construction Company, Masury, Ohio, has been promoted to general superintendent.

The capital stock of the Highland Iron & Steel Company, Terre Haute, Ind., has been purchased by the American Chain Company, Inc., New York.

Frederick W. Renshaw, president of the Globe Seamless Steel Tubes Company, Chicago, died on February 1 at his home in Evanston, Ill., at the age of 39 years.

Donald S. Linton has joined the Warner & Swasey Company, Cleveland, Ohio, having formerly been connected with the Pratt & Whitney Company, Hartford, Conn.

Frank A. Turner, chief engineer of the Becker Milling Machine Company, Hyde Park, Mass., has become chief engineer of the Flexible Automotive Tire Company, Boston.

Charles E. Hildreth, president and general manager of the Whitcomb-Blaisdell Machine Tool Company, Worcester, Mass., has been elected president of the Worcester chamber of commerce.

Harold M. Davis, manager of the advertising department of the Sprague Electric Works of the General Electric Company, New York, died at his home in Brooklyn on February 9, 1920.

Arnold J. Burke, for 16 years connected with the United States armory in Springfield, Mass., has been appointed employment manager of the Greenfield Tap & Die Corporation, Greenfield, Mass.

George W. Diehl, president of the Cincinnati Shaper Company, Cincinnati, Ohio, has sailed for England and France, to establish branches through which the company's foreign business will be handled.

G. C. Cook, general sales manager of the Warner & Swasey Company, has left for a five weeks' trip through the South and to the Pacific coast. He expects to visit about 50 cities and towns before returning.

The Gardner-Bryan Company, Cleveland, Ohio, has been appointed special representative in Ohio, Indiana and Western Pennsylvania for the Precision and Thread Grinder Manufacturing Company, Philadelphia, Pa.

C. B. Ferry, vice-president of the Chicago, Milwaukee & St. Paul, has been elected a director of the Associated Welding Companies, Inc., New York, a corporation formed recently by thirteen electric welding companies.

William R. Mau, general superintendent of the Rich Tool Company, Chicago, has been appointed Chicago district manager of the Vanadium-Alloys Steel Company, Pittsburgh, Pa., with offices at 566 West Randolph street, Chicago.

F. H. Maple, superintendent of the Point St. Charles (Que.) plant of the Canadian Steel Foundries, Ltd., Montreal, Que., has been appointed foundry superintendent of the American Steel Foundries' plant at Alliance, Ohio.

The Sherritt & Stoer Company, Inc., Philadelphia, Pa., announces the opening of new offices, storeroom and warehouse at 2006-8 Market street, where it will maintain a permanent exhibition of machine tools, railway and machine shop equipment.

The Westinghouse Electric & Manufacturing Company has filed plans for the erection of a machine shop, 1,000 ft. long by 100 ft. wide, on Page boulevard, Springfield, Mass., to cost \$250,000: The building will be of brick, concrete and steel, of the saw-tooth type.

William R. Gummere, who for a number of years represented the Independent Pneumatic Tool Company, of Chicago, in Cleveland, Ohio, has again become affiliated with that company at the Pittsburgh branch, which is under the management of Harry F. Finney.

J. A. McLennan, general superintendent of the Link-Belt Company, Philadelphia, Pa., has resigned to become general manager of the McDonough Manufacturing Company, Eau Claire, Wis., which has recently been reorganized and is now manufacturing machine tools.

Howard C. Rose, 827 Ford building, Detroit, representative of the Ingersoll Milling Machine Company, Rockford, Ill., and the Foote-Burt Machine Company, Cleveland, will make an extended tour through Europe in the interests of these companies, for purposes of trade investigation.

Alexander MacDonald Graver, vice-president of the Graver Corporation, East Chicago, Ind., died at his home in Chicago on January 31. Mr. Graver was one of five brothers who control the Graver Corporation, formerly the Wm. Graver Tank Works. He was born at Pittsburgh, Pa., on May 15, 1883, and was educated at the University of Michigan, from which institution he graduated in 1905. He then entered the engineering department of the Wm. Graver Tank Works, where he had charge of the electrical and steam equipment and remodeled the company's manufacturing plant. In 1908 he entered the purchasing department and soon after assumed charge of the purchase of steel plates. From 1910 to the time of his death, Mr. Graver was identified with the sales department of the organization and for the past two years has been virtually sales manager, although holding the title of vice-president of the organization.

A. M. Graver

L. R. Meisenhelter has been appointed special representative of the Houston, Stanwood & Gamble Company, Cincinnati, Ohio, and will devote his entire time to the sale of this company's line of lathes. Mr. Meisenhelter has disposed of his interest in the L. R. Meisenhelter Machinery Company.

The Plant Engineering & Equipment Company, Inc., New York, manufacturers of the Corliss valve steam trap and

other power and heating specialties, announces the opening of an office at 282 South Ferry street, Newark, N. J. M. Wm. Ehrlich has been made New Jersey manager, with a sub-office at Lyndhurst, N. J.

Oscar Nordstrom, formerly district manager of the Norton Company, Worcester, Mass., with headquarters in Cincinnati, is at present taking a training course in the machine division at the Worcester works. H. W. Lehman, Cleveland, has been transferred to Cincinnati to take over the former duties of Mr. Nordstrom.

E. E. Griest, notice of whose appointment as general superintendent of the Chicago Railway Equipment Company, Chicago, appeared in the January issue, was born at Zanesville, Ohio, on November 28, 1882. He entered railway service in 1899 as a clerk in the auditors' office of the Cleveland & Marietta at Cambridge, Ohio. In 1900 he entered the employ of the Pittsburgh, Cincinnati, Chicago & St. Louis as an apprentice machinist in the Columbus (Ohio) shops, remaining in this capacity and later as a machinist until November, 1904, when he entered Purdue University, graduating in 1907. After some time spent in Alaska, he returned to the United States in 1907 as a designer in the engineering department of the Crucible Steel Company of America, Pittsburgh, Pa. In 1908 he was appointed foreman in the Hornell (N. Y.) shops of the Erie and later in the same year he was appointed assistant machine shop foreman in the Fort Wayne (Ind.) shops of the Pennsylvania Lines West. On March 15, 1909, he was promoted to assistant master mechanic, with the same headquarters, and in January, 1915, he was promoted to master mechanic. He retained this position until 1918, when he resigned to become connected with the Chicago Railway Equipment Company, with headquarters at Chicago. In September, 1918, he was transferred to Detroit, Mich, remaining there until his recent promotion.

E. E. Griest

Frank R. Bacon, president of the Cutler-Hammer Manufacturing Company, Milwaukee, Wis., has been elected chairman of a new organization in Milwaukee known as the American Constitutional League, the activities of which will be confined solely to Americanization work and which will embrace all forms of education and publicity in favor of Americanization.

F. Rodger Imhoff, New England representative of the Precision & Thread Grinder Manufacturing Company, Philadelphia, has been appointed field engineer, with headquarters in Detroit, covering the entire country in the interest of the multi-graduated precision grinder. Mr. Imhoff is an expert in thread grinding and has written many papers on that subject.

Arthur G. Henry, metallurgist for the Illinois Tool Works and secretary of the American Steel Treaters' Society since its organization in September, 1918, has resigned from both offices to become special representative for the Vanadium Alloys Steel Company, Latrobe, Pa., with offices at 566 W. Randolph street, Chicago. Mr. Henry has been succeeded

on the board of directors of the American Steel Treaters' Society by W. H. Eisenman, business manager of the society, who in addition also succeeds him as secretary, combining the two offices with the title of executive secretary.

The Booth Electric Furnace Company, Chicago, announces the opening of two new sales offices in addition to the regular district offices already established. One is at Detroit, 805 Hammond building, and is in charge of M. A. Beltaire, Jr.; the other is at Birmingham, Ala., located in the Brown and Marx building, and is in charge of Cassman & Cunningham.

The Imperial Belting Company, Chicago, has opened a special railroad sales department under the direction of A. G. Pickett as general manager and the following have been

A. G. Pickett

appointed sales engineers: Edward H. Willard, David L. Jennings and William D. Otter, all formerly with the H. W. Johns-Manville Company; William G. Willcoxen, formerly associated with the Boss Nut Company, Chicago, and Edward A. Woodworth, formerly secretary of the Committee on Standards for Locomotives and Cars of the United States Railroad Administration. A new office has been opened in the Merchants' National Bank building, St. Paul, Minn., in charge of Blake C. Hooper. A. G. Pickett was born at New London, Mo., on July 12, 1888. In 1911 he became connected with the sales department of the National Refining Company, Hannibal, Mo. Later in the same year he was appointed special power plant representative for the H. W. Johns-Manville Company at New York. On January 1, 1916, he was promoted to assistant manager of the power specialties department and in 1917 was promoted to manager of that department, which position he retained until August, 1919, when he resigned to become connected with the sales department of the Imperial Belting Company.

The Hauck Manufacturing Company, Brooklyn, N. Y., announces the removal of the Pittsburgh office of the Hauck Burner Service Station from 2930 Penn avenue to 105 Wood street. The Boston and Cleveland service stations have also been moved to larger quarters, the former from 70 High street to 149 Berkeley street, and the Cleveland office from 2114 Superior viaduct to 1106 Walnut avenue.

A. A. Blue has been placed in charge of the heat treating department of the Duff Manufacturing Company, Pittsburgh, Pa. Mr. Blue is a graduate of the chemical engineering department of Cornell University. For two years he was connected with the Midvale Steel Company in the heat treating department, and during the war served as assistant superintendent of heat treating and forge shop in the gun plant of the Watertown arsenal.

The American Chain Company, Bridgeport, Conn., has purchased the control of the Page Steel & Wire Company, with mills at Monessen, Pa., and Adrian, Mich., and the business will be continued as heretofore. The new officers elected under the reorganization of the company are Walter B. Lashar, president; William T. Morris, vice-president; Wil-

mot F. Wheeler, treasurer; John E. Carr, assistant treasurer, and William M. Wheeler, secretary. E. C. Sattley, general manager of the Page Steel & Wire Company, will continue in that capacity with office in Pittsburgh, Pa.

C. N. Kell, has been appointed assistant to the general manager of the forge department of the Duff Manufacturing Company, Pittsburgh, Pa., manufacturer of lifting jacks. For the last eight months he has been assistant to the general superintendent of this company in charge of efficiency work. Mr. Kell designed the equipment of the Rock Island arsenal for testing the recoil mechanism of the French 75-mm. gun. His previous experience included work as mechanical engineer with the Mandel Corporation of Chicago, and an assistant superintendent of the Denny Tractor Company, Cedar Rapids, Iowa.

F. J. Mawby, who was formerly connected with the sales force of Manning, Maxwell & Moore, Inc., and located at the New York office for a number of years, severed his connection with that company on February 1, 1920, and is now a member of the sales organization of the Cincinnati Shaper Company and the Cincinnati Gear Cutting Machine Company, Cincinnati, Ohio. During the war Mr. Mawby did a great deal of engineering work in connection with equipping shops for the manufacture of ammunition, guns and gun carriages for both the United States and foreign governments, and was responsible for the development of a number of special machines for the rapid production of time and high explosive fuses.

B. G. Koether has been appointed vice-president of the Hyatt Roller Bearing Company, Detroit, Mich., in entire charge of the company's sales and advertising departments.

B. G. Koether

At present located at Detroit, Mr. Koether will leave in a short time for Harrison, N. J., there to establish headquarters and take up his new duties. Mr. Koether entered the employ of the Hyatt Roller Bearing Company 18 years ago as accountant and in a short time was promoted to the position of purchasing agent. He was made assistant sales manager at Harrison, N. J., and in 1910 went to Detroit to assume the duties of sales manager. Later he became the head of

the motor bearings division and for several years past has been a director of the company. Mr. Koether is a member of the Detroit Board of Commerce and the Detroit Section of the Society of Automotive Engineers.

The Williams-Hayward Company has been incorporated at Chicago for the manufacture of varnishes, enamels and paint specialties. LeRoy A. Williams, for 21 years associated with the railroad department of the Flood & Conklin Company, Newark, N. J., is president of the new company and Oscar C. Hayward, for 18 years manager of railroad sales of the Tousey Varnish Company, Chicago, is vice-president. Otto Woldt has been appointed head of the manufacturing department and Max Huhnholz superintendent of the enamel and paint specialties department. The company has purchased a modern varnish factory with a capacity of approximately 500,000 gal. of varnish annually, to which complete mills for the manufacture of enamels and

paint specialties have been added. The main offices and plant are located at 2526 West Van Buren street, Chicago.

Westinghouse Air Brake Company

Joseph R. Ellicott on January 1, 1920, retired as eastern manager of the Westinghouse Air Brake Company, but has been retained by the company in a consulting capacity. He has been succeeded as eastern manager by Charles R. Ellicott, as briefly noted in the January issue. Mr. Ellicott was born in Chicago on November 13, 1881. He received his early education in the public schools of New York, and was graduated from Yale-Sheffield School in 1902. The same year he entered the employ of the Westinghouse Air Brake Company, at Wilmerding, Pa., as special apprentice. After serving two years in the engineering and commercial departments, he was made representative in the New York office, covering both commercial and engineering work. In 1913 he was made assistant eastern manager of the Westinghouse Air Brake Company and the Westinghouse Traction Brake Company. On January 1, 1920, Mr. Ellicott was made eastern manager of both companies.

Robert Burgess has been promoted to southeastern manager, with office in Washington, D. C. He was born in New Haven, Conn., and attended public school there, graduating

of the safety car equipment. Mr. Beck's study of electric railway operation has made him an authority on transportation problems.

John B. Wright has been promoted to assistant district manager in charge of the Pittsburgh office district. He was born on July 27, 1857, in Pleasantville, Pa., and received his education in the public schools there and at Central State Normal School, Lock Haven, Pa., graduating in 1896. He worked for about 18 months with the Cambria Steel Company, at Johnstown, Pa. In February, 1899, he entered the service of the Westinghouse Air Brake Company, at Wilmerding, Pa., as a clerk in the engineering department. After serving for some time as chief clerk in that department, he was transferred to the general office in charge of engineering correspondence, and later was made assistant to the vice-president. In May, 1919, he was appointed assistant southeastern manager.

A. K. Hohmyer has been promoted to the position of assistant western manager, Chicago, Ill. He was born in Pittsburgh, Pa., and attended the public schools of that city. In February, 1901, he started to work for the Westinghouse Air Brake Company, in the general office, as office boy. He passed rapidly and successively to the order department, engineering department, and other departments until Febru-

C. R. Ellicott

Robert Burgess

F. H. Parke

from grammar and high schools. He began railway service with the Louisville & Nashville under the late Pulaski Leeds as machinist apprentice. On completion of his apprenticeship course he continued with the company in the various capacities of air brake repairman, roundhouse foreman, locomotive fireman and engineer, and general air brake inspector. He joined the Westinghouse Air Brake Company organization in 1893 as assistant instructor in the company's air brake instruction car. In 1896 he was assigned to the southern district, with headquarters at Atlanta, Ga., and for several years at Richmond, Va. He has since that time represented the company continuously in that district as mechanical inspector and commercial representative.

Carl H. Beck has been appointed assistant eastern manager at New York. He was born in Butler, Pa., and was graduated with the class of 1905 in mechanical engineering from Pennsylvania State College. The same year he entered the special apprenticeship course prescribed by the Westinghouse Air Brake Company. He was a specialist on the introduction of the ET locomotive brake equipment, personally superintending the installation of this equipment on some of the first locomotives to be so equipped at the Baldwin and American Locomotive Works. In 1910 he was made commercial representative in the electric railway field, becoming prominently identified in the development and introduction

ary, 1909, when he was transferred to the Chicago office as office manager. He remained in that position until 1913, when he was appointed commercial representative. He continued to work in that capacity until January 1, 1920, the time of his promotion to assistant western manager.

William G. Kaylor has been promoted to representative of the newly organized export department of the Westinghouse Air Brake Company, with headquarters in New York. He was born in Indianapolis, Ind., attending public school there and graduating from the Manual Training High School. He graduated from Purdue University in 1905, and entered the employ of the Westinghouse Air Brake Company at Wilmerding, Pa., as a special apprentice. The first year he served in the experimental and engineering departments, and the following year in field work, covering the equipment of electric locomotives for the New York Central at the various building plants throughout the east. He also installed the first air brake equipment on the all-steel passenger cars in interurban New York City service. He acted as mechanical expert in connection with the introduction of electric service on the main lines of both the New York Central and New York, New Haven & Hartford railroads. After serving as assistant for several months to the resident engineer, he became actively engaged in November, 1911, in commercial work, specializing in the traction brake field.

F. H. Parke, resident engineer, southeastern district, has been promoted to general engineer, with office at Pittsburgh, Pa. He was born in 1869 at Waterloo, N. Y., and was educated in the public schools at Binghamton, N. Y., and St. John's School, Manlius, where he prepared for a course at Cornell University. He was graduated from Cornell in mechanical engineering in 1892, and immediately entered the service of the Westinghouse Machine Company at Pittsburgh, Pa., first as draftsman and afterwards as engineer of tests. In 1898 he took service with the Westinghouse Air Brake Company, spending the first four years in Petrograd, assisting in the installation of the Westinghouse Air Brake plant being erected there to handle the Russian railway business. Returning to the home office at Wilmerding, Pa., he was given charge of the publicity department and afterwards was made industrial engineer, in which capacity he served until 1911. He was then made resident engineer of the southeastern district.

T. W. Newburn, assistant resident engineer, southern district, at Pittsburgh, has been promoted to district engineer of the southeastern district, with office at Washington, D. C. Mr. Newburn was born near Hoopston, Ill., and received his early education in the country schools and at Greer College. He was graduated from Purdue University with the 1902 class in mechanical engineering, and immediately entered the service of the Cambria Steel Company, Johnstown, Pa. In August, 1902, he entered the employ of the Westinghouse Air Brake Company, being assigned duties in the mechanical and engineering departments of its Wilmerding factory. He was connected later with the Cleveland office, then with the Columbus office as mechanical expert in connection with electric railway brakes. In 1914 he was assigned to the Pittsburgh office as assistant resident engineer, where he leaves to take up his new duties.

Joseph H. Woods of the commercial engineering department at Wilmerding has been promoted to engineer of the newly arranged export department. He was born in February, 1886, at Hamilton, Ont. After graduating from the public schools and Hamilton Collegiate, he was employed as an apprentice in a machine shop for three years, and then entered the mechanical drawing room of the Canadian Westinghouse Company, Ltd. In 1908 he was transferred to the air brake department. The following year he entered the engineering test department, and in 1911 was appointed assistant engineer of tests. In 1915 he was transferred temporarily to New Jersey as general foreman of the Air Brake Company's shrapnel loading plant. On completion of the shell loading work in 1916 he returned to Wilmerding to take up duties in the general office division of the engineering department.

Joseph C. McCune, special engineer at Wilmerding, is now assistant to the eastern district engineer, with office in New York. He was born in Brilliant, Ohio, in 1890. He attended the high school at Steubenville, Ohio, and in 1906 entered Washington and Jefferson College, taking preparatory work for one year. He graduated from Cornell University with the class of 1911, receiving the degree of mechanical engineer. He entered the employ of the Cutler-Hammer Manufacturing Company, Milwaukee, Wis., and later served in the traffic department of the Pittsburgh Railway Company. In 1913 he joined the Westinghouse Air Brake Company as assistant to the chief engineer, Dr. Walter V. Turner. In 1915 he was transferred to the New York office as mechanical expert, charged with the development and satisfactory operation of the new air brake equipment then being applied to the subways of Greater New York. In 1916 he served for five months at the Mexican border with the 7th Regiment, N. Y. N. G. Returning from this service, he was commissioned first lieutenant in the Engineer Officers' Reserve Corps, and upon the outbreak of the war with Germany

was ordered to active duty. He was an engineering instructor at the 1st, 2d and 3d Officers' Training Camps, and in May, 1918, was assigned to the 603d Engineers, going overseas with this organization and remaining abroad for ten months. Returning to this country, he re-entered the employ of the Westinghouse Air Brake Company as special engineer at Wilmerding.

The Western Electric Company, Inc., 195 Broadway, New York, has reorganized its railroad representative staff under the direction of George H. Porter, manager of the railroad department, as follows: The Western district representatives are: J. P. Casey, St. Louis, Mo.; W. J. Schott, Kansas City, Mo.; George Chestnut, Houston, Tex.; G. N. Hoffman, Salt Lake City, Utah; W. H. Laufenberg, Denver, Colo.; J. E. Coad, Dallas, Tex. Those for the Coast district are: I. A. Shorono, Seattle, Wash.; J. G. Loomer, Los Angeles, Cal.; H. A. Case, San Francisco, Cal.; Jack F. Ryan, Portland, Ore.; J. H. Kelley, Tacoma, Wash.; C. A. Martin, Spokane, Wash. Central district: Otto Danielson, Chicago; E. B. Elliott, Chicago; A. J. McCall, Omaha, Neb.; Tom Wheatley, Cleveland, Ohio; R. D. Eves, Cincinnati, Ohio; W. H. McGann, Cincinnati, Ohio; R. W. Tenbroeck, Toledo, Ohio; C. E. Roberts, Indianapolis, Ind.; W. H. Tompkins, Milwaukee, Wis.; E. B. Denison, Minneapolis, Minn.; G. E. Brown, Duluth, Minn.; A. W. Hillis, Detroit, Mich.; A. Schwenck, Grand Rapids, Mich. Eastern district: Oscar Lepper, Pittsburgh, Pa.; A. B. Thomson, New York; Charles R. Wharton, Philadelphia, Pa.; Fred Jaeger, Philadelphia, Pa.; James Stuard, Philadelphia, Pa.; E. R. Morgan, Boston, Mass. Southern district: William Lancaster, Richmond, Va.; H. B. Stanton, Savannah, Ga.; W. R. Phillips, Jacksonville, Fla.; J. W. Smith, Atlanta, Ga. A. L. Frankenberger remains at St. Paul, Minn., and Sidney Greenfield at Baltimore, Md.

Arthur Elliot Allen has been appointed district manager at New York for the Westinghouse Electric & Manufacturing Company, to succeed Edward D. Kilburn, who has been elected vice-president and general manager of the Westinghouse Electric International Company. Mr. Allen is a native of Toronto, Canada, and received his education in England and also in this country. In June, 1902, he entered the employ of the Westinghouse Electric & Manufacturing Company at its Newark works, subsequently being placed in charge of the test department, where he remained until 1910. In that year Mr. Allen was loaned by the

A. E. Allen

management of the company to the International Electric Protection Company, for which company he acted as chief engineer. After completing that temporary work, he returned to the employ of the Westinghouse company, and on December 1, 1915, Mr. Allen was appointed manager of the supply division of the New York office, which position he retained until he joined the Canadian Overseas Forces in October, 1917. After being honorably discharged from the army he returned to the New York office of the Westinghouse company as executive assistant to the manager, from which position he was promoted to manager.

TRADE PUBLICATIONS

ASBESTOS.—In the December issue of the *Railway Mechanical Engineer* there appeared a short review of the first number of *Asbestos*, a monthly magazine, in which it was stated that the publisher is the Magnesia Association of America. This statement is erroneous, as the booklet is published by Secretarial Service, 721 Bulletin building, Philadelphia, Pa.

ELECTRIC CRANES.—A bulletin entitled *Lane Electric Cranes*, has been issued by N. B. Payne & Co., 25 Church street, New York, agents for cranes manufactured by the Lane Manufacturing Company, Montpelier, Vt. The bulletin fully illustrates and describes several styles of cranes in which steel girders or heavy timbers of yellow pine are used, and contains a complete set of specifications.

FURNACE BURNERS.—Bulletin No. 119 of the Hauck Manufacturing Company, Brooklyn, N. Y., describes in detail the many different types of oil burners manufactured by this company and illustrates practical applications of the burners to various types of furnaces. In addition, a number of sketches are included, suggesting other ways of applying Hauck burners, and throughout the book are given results of tests, prices and service data.

AUXILIARY DEVICES GOVERNOR.—Instructions for the installation and care of the auxiliary devices governor have been published for distribution by the Westinghouse Air Brake Company, in a 12-page booklet bound with stiff covers and designated as *General Instructions No. 2360*. The construction and operation of the governor is described and is supplemented by sketches with the parts numbered and named. Instructions are also given for properly adjusting the pressure.

BOILER FEED CONTROL.—A 24-page booklet entitled *Saving Fuel Automatically and Scientifically in the Boiler Room* has been published by the Northern Equipment Company, Erie, Pa. It is based upon matter that was prepared for the United States Fuel Administration during the war and compares hand and mechanical feeding with mechanical regulation, as performed by the Copes regulator, being illustrated with a number of charts and diagrams to emphasize the value of scientific control.

BRAKE ROD JAW.—The Schaefer Equipment Company, Pittsburgh, Pa., describes and illustrates, in a four-page pamphlet, the Schaefer drop-forged brake rod jaw for attachment to brake rods. The method of applying the jaw is simple and is illustrated. It is claimed that the jaw may be removed and reattached without any danger from failure and that it may be applied and reapplied without loss. The pamphlet also shows the results of pulling tests on six different jaws fastened on $\frac{7}{8}$ -in. brake rods, which were made at the Pittsburgh Testing Laboratory.

VALVES.—Catalogue and price list No. 10 of Nelson valves has been issued by the manufacturers, the Nelson Valve Company, Philadelphia, Pa. The book contains 156 pages, 5 in. by $7\frac{1}{2}$ in., and is bound in cloth. It is divided into three parts, devoted respectively to bronze, iron and steel valves, with an introduction describing the general features of the design and service rendered. The valves are made in gate, globe check and non-return patterns for practically every class of service found in power plant work, etc. The book contains numerous illustrations and the data is conveniently arranged.

DRAFT GEARS—Force and Its Applied Principles, is the title of a 28-page booklet, bound in stiff paper covers, which has just been issued by the Union Draft Gear Company, Chicago. The booklet explains concisely and non-technically the elementary relationship of force and motion, defining the terms used. How these principles apply to the operation of the draft gear is then set forth and the booklet concludes with a discussion of draft gear capacity and the essentials of draft gear testing. A table for the conversion of miles per hour into height of fall in feet, for use in calculating the energy in moving cars for speeds from 1 to 10 miles per hour by half mile intervals, is included.

INDUSTRIAL MANAGEMENT.—L. V. Estes, Incorporated, industrial engineers, Chicago, have published a small booklet entitled *Human Relations in Industry*, for the purpose of pointing out the underlying principles of personal relations and industrial management that are essential to industrial harmony and maximum production. It contains a statement showing the trend of present conditions and the need for definite action by employers, and outlines in a general way the procedure necessary for putting in effect plans tending toward a betterment of human relations in industry.

STEEL PIPE.—National Bulletin No. 24A has been issued by the National Tube Company, Pittsburgh, Pa., and shows graphically the remarkable growth of the steel pipe industry from 1888 to the present time. The chart indicates a decrease in the production of wrought iron pipe during this period. Quotations are given from the editorial columns of three current periodicals in the iron field to show the reasons for the popularity of steel pipe and its probable permanence. Included in the bulletin is a chart showing the relative production of wrought-iron and steel skelp from 1888 to 1918.

DROP FORGINGS.—J. H. Williams & Co., Brooklyn, N. Y., manufacturers of Superior drop forgings and drop-forged tools, have issued the seventeenth edition of their catalogue, containing 160 pages, 4 in. by 6 in., fully illustrating and describing their standard stock specialties. These include new lines of "Agrippa" set screw pattern turning tool holders, "Agrippa" boring tool posts, "Vulcan" forged-cutter tool holders, and several new sets of drop-forged wrenches. The book also contains a description of the drop-forging process in simple, non-technical style for the benefit of those not conversant with its details.

OPPORTUNITIES FOR TECHNICAL GRADUATES.—Opportunities for technical graduates are very thoroughly explained in an illustrated pamphlet bearing that title, recently issued by the Westinghouse Electric & Manufacturing Company. This booklet describes, in considerable detail, the plan which has been developed by this company for the training of the graduates of technical schools at all of its various works. In the booklet is included a list of prominent Westinghouse men who originally entered the company as graduate students, as well as a complete list of schools from which over 5,000 students have entered the employ of the company.

INSULATION PRODUCTS.—The Franklin Manufacturing Company, Franklin, Pa., has issued a 77-page catalogue entitled *Heat Insulations*. This catalogue contains brief descriptions of the company's insulation products, including 85 per cent magnesia pipe covering, railroad special pipe covering, Franklin carlining, asbestos millboard, wool felt covering, etc. Packing and shipping directions are included. The back part of the catalogue contains considerable engineering information in the form of tables and data to be used in the solution of heat insulation problems. Instructions for the use of these tables are given and several concrete examples are worked out.

Railway Mechanical Engineer

VOLUME 94, NUMBER 4

New York—APRIL, 1920—Chicago

ESTABLISHED IN 1832

Published Monthly by Simmons-Boardman Publishing Co., Woolworth Building, New York, N. Y. Subscription price, United States, Canada and Mexico, \$2.00 a year; foreign countries, \$3.00 a year. Entered as second-class matter, January 27, 1916, at the post office at New York, N. Y., under the Act of March 3, 1879.

A FEW YEARS AGO

The Security Arch saved \$3⁵⁰ in coal per 100 miles per engine.

TO DAY

The Security Arch saves \$7⁰⁰ in coal per 100 miles per engine.

Equip your old engines!

Portable tools driven by compressed air are in such general use in railroad shops that the possibility of securing better results with a device of some other type is seldom considered. In view of the high cost of pneumatic power and the serious leakage that exists in the majority of air lines, it is quite probable that for many uses electric drills would prove more economical than air drills. The most important advantage of electric tools aside from the saving in power is the substitution of wires for piping and hose. The power lines can be extended very readily, power losses are decreased, the wires are easily handled and the expense of installation and upkeep compared with the cost of maintaining air pipe lines and pneumatic hose is considerably less. The even turning moment and absence of vibration in the tools are also important advantages. On the other hand, an electrically driven tool is liable to burn out if the motor stalls, and for that reason ample capacity must be provided or automatic reclosing circuit breakers must be used in each circuit.

Electrically Driven Portable Tools

Some roads have applied electric tools here and there through the shop, but very often the conditions under which they were used have been so unfavorable that the tools did not have a chance to show their worth. Much of the prejudice against electric tools that exists in some shops today is due to the improper application of universal motors. This type of motor was introduced to meet the demand for machines that could be used with either direct or alternating current, but is not well adapted for heavy portable tools. Universal motors should never be used for reaming, and on machines used for drilling they should be limited to sizes not larger than 1/2 in. For general work, series motors for direct current, or induction motors with high slip for alternating current are most suitable. These types possess characteristics that make them more satisfactory (for many purposes) than air tools.

In railway repair shop practice the experienced tool dresser is so important that he might almost be said to be invaluable.

Scientific Tool Hardening

Almost every repair shop has developed at least one tool dresser who by years of experience has become expert in hardening hand chisels, cape chisels, beading tools and all sorts of small tools. Given a known steel plus a knowledge of the work to be done, and it is surprising how satisfactory and reliable a tool can be turned out—sometimes. The difficulty is that the tool dresser must depend upon his eyesight to estimate temperatures and upon rule of thumb methods to harden the tools. His equipment consists of a forge and anvil; sometimes a small power hammer and suitable cooling tanks are available, but too often there is no accurate temperature recorder.

While tool dressers of the type referred to do the best they can with the equipment provided and often succeed in producing a tool which is not only strong but holds its cutting edge under severe duty, the opposite usually is true. A uniform product is impossible, and if one tool is good the next is likely to be poor. It is practically useless to buy high-grade steel and then profit by only part of its good qualities because of improper and non-uniform methods of hardening. The solution of the problem is to provide modern, up-to-date equipment, including some type of muffle furnace arranged for accurate temperature control, an indicating pyrometer to gage the temperatures and suitable oil, lead and brine baths for drawing. In any shop of medium or even small size the saving effected by installing such equipment will be found more than sufficient to pay the carrying charges on the investment involved.

To prove the relative merits of scientific heat treatment of steel versus guesswork methods, an extensive series of tests was made recently in a large, well-equipped shop. A stand-

ard, high-grade tool steel was used and similar tools, hardened by the two processes, were tested under actual working conditions. A mixture of 75 per cent lead and 23 per cent tin with a melting point of approximately 450 deg. F. was used for the lead bath, the bath being well covered with charcoal to prevent oxidation and to keep the lead from adhering to the tools. In every case 24 identical tools were selected. Twelve were heated in furnaces equipped with indicating pyrometers and the other 12 were heated in furnaces without pyrometers, or in forges, the temperatures being estimated by the operator. The same man did the heating, hardening and tempering of both lots of tools.

Twelve hand chisels were heated in a lead furnace to 1,440 deg. F., quenched in a 10 per cent brine solution and drawn to a deep blue (580 deg. F.) in the lead alloy, checking the temper in oil. The chisel heads were reheated from 1,300 to 1,350 deg. F. to relieve forging strains. An old locomotive axle was used for testing purposes and 3,000 blows were struck per chisel with a 1½-lb. hammer. At the conclusion of the test the cutting ends of the chisels showed no signs of wear, while the chisel heads were mashed down ½ in. Of the 12 tools made without the pyrometer three showed fire cracks, four finished the test and the remainder broke in service because of irregular temperature in heating and forging.

In the next test 12 pneumatic beading tools were heated in a lead bath to 1,440 deg. F. The working or boot ends were drawn to 470 deg. F. in oil, which is equivalent to a dark straw color; and the shank temper was drawn to 520 deg. F. in oil, which is equivalent to a purple color. Each end of the tool was hardened separately and then drawn to the proper degree to insure a tough center. The quenching was done in a 10 per cent brine solution, at about 60 deg. F. The average service life was 2,850 flues per tool and no tools were broken. The second set of 12 beading tools, on the other hand, produced only 863 flues. Three tools broke in the shank, two at the radius of the boot ends and the fractures showed a coarse structure because the temperature limit had been exceeded.

These tests demonstrate conclusively the large increase in efficiency possible by the use of definite scientific methods of heat treating and hardening. They explain why the more progressive steel companies are co-operating with their customers in installing modern appliances for heat treating steel. The results also furnish the strongest evidence why such equipment is needed in every shop.

The paper presented at the March meeting of the Central Railway Club and the discussion which followed it will bear careful reading, especially by those who are inclined to be pessimistic about the labor situation. Reviewing casually the outstanding developments of the last few months, there seems to be ground for pessimism. In many shops production is near the low mark, controversies brought about by the national agreement are still unsettled, and the shop organizations are now asking for an advance in wages which would add still further to the cost of maintaining equipment.

Despite these facts, the men who spoke at Buffalo were optimistic regarding the solution of the present labor problem. The basis for their confidence was evidently a firm belief in the ultimate good sense of the American workingman. Labor has suffered from poor leadership and some have been misled by radicals who have tried to persuade the men that they could get something for nothing. The discussion of economic problems in the daily press has had its effect, however, and today the average workingman realizes that his share of the necessities and luxuries of life depends almost wholly on how much is produced. With this fact gen-

erally recognized by the men there is little likelihood that the railroad officers will find any opposition to increased production if the workers are appealed to in the proper spirit. Further education may be required before the situation becomes satisfactory, but the present trend of events is at least encouraging.

Granting that the average workman realizes that high production is necessary, it may be well to inquire what is being done to interest the men in increased shop output. The officers in charge of the shops are always greatly concerned when there is a falling off of production. The supervisors must obtain results by influencing the men in their organization. The lack of personal contact makes it hard for those in charge to pass their own spirit on to the men, but there are methods of arousing interest and getting results. It is natural for men to take pride in the organization of which they are a part. If the matter of increased production is approached in the same spirit as a baseball contest, if the natural desire to excel in any branch of endeavor can be brought to the fore, the officers can put the matter of increased output up to the men and there will be no question about the result. To apply this principle successfully a fair measure of shop efficiency and accurate records are essential. No one will take a keen interest in a game if the rules are unfair or if the score is not kept correctly. The cost of repairs is not a fair measure at the present time, but the man-hours per unit of work furnish a satisfactory means of gaging shop efficiency. Charts or diagrams to show the variation in output conspicuously placed around the plant and systematically brought to the attention of the employees have proved helpful in some shops. There has been a great deal said about the present low efficiency of labor, but in one case at least where comparative records were established they resulted in an increase in production which brought the output well above the previous mark.

Putting It Up to the Men

There is no doubt of the important economies effected in automotive and other industries from the introduction of modern grinding machinery and methods. Why should not railway shops benefit in a similar way. Grinding makes possible higher production and decreases the unit cost. More accurate work can be done and the extensive use of ground crank shafts and bearings proves that there is no inherent objection to grinding on this score. The old argument that particles of grit adhere to and become imbedded in a ground steel surface has been refuted not only by experience in the automotive industry, but by the experience of several railway shops that have practiced the grinding of axles and crank pins for a long time with satisfactory results.

Railway Shop Grinding Needs

At no time in the history of American railroads has there been a more crying need for increased output in both railway repair shops and roundhouses than right now. Why then do we find such a lack of modern grinding machines in railway shops, when, according to machine tool experts throughout the country they are absolutely necessary to the most economical shop operation?

Two answers may be given to this question. There are still a few machine shop men who do not believe in grinding methods applied in railway shops because their fathers did not use those methods. Needless to say men of this type, whose minds always dwell in the past, are in the small minority. Most machine foremen are not only willing but anxious to install any machine or method that will help increase production. A second large group of men object to grinding because their entire acquaintance with grinding ma-

chinery has been acquired in operating the antiquated machines in their individual shops and in vainly trying to get production results.

For example, the main repair shop of a certain eastern railroad is provided with two grinding machines, both eight or ten years old and entirely too light for the work to be done. The guide grinder, in addition to being too light, is of the horizontal spindle type and takes from two to four hours to grind an 84-in. guide that could be ground on a modern machine in approximately one hour. The machine foreman in charge uses this machine to its capacity, but merely as a means of reducing the planer work, and it is no wonder he does not have a high opinion of guide grinders.

The other production grinding machine in this shop is a piston rod grinder used occasionally to grind valve stems. In addition to being too old and light for accurate work the machine is not large enough to swing the heaviest class of piston rods, which accordingly have to be turned and rolled on an engine lathe. The face of the grinding wheel used with this machine is only 1½ in. wide and to call the grinder a production machine is a serious misnomer.

Conditions similar to those outlined above are only too common in railway shops and the fault should not be laid primarily at the door of the machine foreman in charge. He is not necessarily an old fogey with Chineselike respect for his ancestors and their ways. More likely than not he has placed his requisition for the tools necessary to bring his shop up to a modern production basis and, while waiting for the new tools, is using his old equipment to the best advantage possible.

For various reasons during the past two years it has been difficult and almost impossible to get the new machinery needed for efficient shop operation but the situation has now changed. More capital is available for additions and betterments and the absolute necessity for improved facilities is apparent to all. Within the past three weeks orders for \$100,000 of new machine tools have been placed by each of two different railroads in the East and definite inquiries have been made by several other roads.

It is earnestly urged that those responsible for railway shop output look into the possibility of increased production and decreased costs by the more general use of grinding machinery. For such operations as truing piston rods, valve stems, guides and links, machining journal bearings, crank pins and other important parts, less material is removed by the grinding operation than by any other. This insures a quicker job at less cost and a longer life for the part ground. The resultant saving in material, labor and time can be computed in dollars and cents and will more than pay carrying charges on an investment in new grinding machinery.

COMMUNICATIONS

CAR DEPARTMENT APPRENTICES

CHICAGO.

TO THE EDITOR:

I was glad to read your editorial in the December issue of the *Railway Mechanical Engineer* and hope that it will be the means of awakening others to the present situation in the car department of railroads all over the country. If not through the training of apprentices, from what source are the

men to be recruited who must man the car shops in the future? House carpenters and others eligible for employment as full-rated car men have seldom had any experience in car work. How are they to get such experience?

If car men are to be recruited from the ranks of apprentices, is the present schedule of work, the length of the course or the rate of pay sufficiently attractive to induce enough young men to take up this work? Will not all three of these features need to be changed?

You state that perhaps it was the intention that a young man desiring or perhaps needing a higher rate of pay than that provided for regular apprentices might first work two years as a helper and then serve three years as a helper apprentice, the increased earnings offsetting the greater time required to learn the trade. But is there any assurance that if he starts in as a helper that in two years he will be advanced to a helper apprenticeship? Are not helper apprentices to be selected in the order of seniority? Will not the majority of helpers now in the car shops be too old for apprenticeships before they are eligible? Moreover, the majority of boys at the age at which they enter upon other

What Do You Think?

Many valuable suggestions in the interest of increased economy and efficiency will be found throughout this issue. You may not approve of some of the methods described or you may have concrete data or information that will prove their value. Perhaps you can improve upon them or offer better suggestions. If so, tell the Editor.

To secure the co-operation of the shop mechanics Mr. McManamy in the article on page 233 advocates forming a shop committee. What do you think of the plan? Will it work?

Is there really anything to all this talk about modern apprenticeship methods in a railroad repair shop? Mr. McManamy seems to think so. (See page 235.) What has been your observation and experience?

A new type of grain car is described on page 209. Would it help in handling the grain traffic on your road?

Are you following the series of articles on the inspection of freight equipment by Mr. Sillcox? Can you add something of value to this series? If you can, the editor wants to know about it.

Can you apply the method of graphic production control described on page 227 in your own shop?

Will the information regarding heat treating methods in the article on page 236 help improve your blacksmith shop practice?

All these articles are intended to be of direct assistance to the readers. What do you think about them? The editor wants to know and will really appreciate brickbats more than bouquets if they will help him to make the *Railway Mechanical Engineer* more effective.

apprenticeships are not sufficiently developed physically to be strong enough for the heavy work of the freight car shops.

Should there not be a different course for apprentices preparing for work in the coach or cabinet shop from that given those being trained for freight car work? Would those capable of doing the former be content with the latter?

Would not a shorter course, say two and one-half or possibly three years, be sufficient for training freight car men, and with such a course should not the age limits be changed and the rates of pay increased so as to make such a course more attractive to those of maturer years, physically strong enough to meet the full requirements of the freight car shop?

I believe the present situation a serious one and the questions raised worthy of careful consideration.

HANDHOLES Vs. WASHOUT PLUGS

New York.

TO THE EDITOR:

The editorial which appeared in your January issue under the title "Accidents due to Washout Plugs," raises a question of great importance. There is no doubt that a plug in a boiler for washout purposes is a very unsatisfactory arrangement and a very dangerous one, especially when one considers the large diameters of the arch tube plugs in a modern boiler. Every time a washout plug is taken out and put back in, the fine thread wears a little; very often a rod is used for shaking the scale off the sheets; when put through the threaded opening in the boiler sheet and turned around a few times, the rod damages the fine thread and the crossing of threads by screwing the plug in is quite probable. For these reasons the locomotive practice of many European countries forbids the application of screwed washout plugs in locomotive boilers and prescribes the use of handholes only.

In a country where plugs were practically unknown for the last 25 or 30 years, a few hundred locomotives arrived

Handholes Used on Russian Locomotives

during the war from abroad with screwed washout plugs. Within less than a year two accidents have taken place; I am familiar with one of these. The fireman was scalded to death as a result of an attempt to tighten a leaky arch tube washout plug in violation of the rule existing on the road, that no washout plug should be tightened under steam—but evidently the temptation to stop leakage overpowered the poor fireman.

Attached you will find a drawing of a Russian standard washout handhole, which is applied in the corners of back sheets and throat sheets and in the front tube sheets on all Russian locomotives. A brass bushing with an elliptical hole is screwed in the sheets permanently and a corresponding elliptical inside cover is put through the bushing and secured in position by means of an outside clamp, washer and nut. The cover is kept tight from inside by the steam pressure and a copper or lead gasket. This makes a very substantial construction, which is absolutely safe. Leakage occurs very seldom, and the tightening of the nut with a regular wrench in case of leakage is quite permissible.

For the arch tube openings in the back head and throat sheet, handholes of the same type are applied, but of a larger size, the average outside diameter of the threaded

bushing being 4 5/16 in., and the elliptical opening 3 in. by 2 13/16 in. Two hundred Decapods built for Russia, which were turned over temporarily to the United States Railroad Administration, have handholes of the type described, and I have never heard any complaint from any of the roads where they are running with reference to the handholes. The handholes are sometimes criticized as taking up more time for putting in place than the plugs; but the difference, which amounts only to a few minutes per handhole, is very small as compared with the time necessary for the complete washout of a boiler. Besides that, this criticism must be put aside in view of the great advantage of the handholes—avoiding accidents and sparing human lives. During the fiscal year ending June 30, 1919, 30 accidents occurred due to washout plugs, resulting in one man being killed and 34 injured. Is it not worth the trouble to adopt the handholes for washout openings in the locomotive boiler?

A. LIPETZ,

Russian Mission of Ways of Communication.

I. A. DEFENDS THE CHIEF CLERKS

While Jap detector are investigating RR shop efficiency he learn of magnificent treatment handed to Chief Clerks.

Learn Chief Clerk are regarded Supernumary by Soviet Unions and as such it becomes bounden duty to fight own battle. Difficult to accomplish as aforesaid Unions maintain strangle hold on Golden Eagles and hand to Cobbler, who are made Mechanic by decree of Soviet aided by Imperial Government Wage Board.

Chief Clerk, before the German brain storm impel Imperial Government to defend Sacred Rights, received \$90 to \$100 per month, while clerks \$45 to \$70 per month. By unknown patented process of Imperial Wage Fixers, fact is established

Chief Clerks Register Despair

that least a clerk must have to outfit with filmy draperies effected by haughty girls are \$87.50. Supplement No. 7 to G. O. 27 which set forth this decree, also provide for married chief clerk with wife and children bountiful sum of \$115 to \$125 per month.

Efforts secure substantial justice are no avail. Chief Clerks register Despair. However, continue to keep Hon. MM posted what are of interest in your esteemed journal, latest instructions S.M.P. on applying spring seats for Engineers Soviet, labor turnover shop, newest ruling of wage adjustments, etc., wondering "How long, O Lord, how long will one suit last," as he are impotent to provide otherwise. Chief Clerks hopeful return RR March 1 make possible securing much needed new suit, if not must stay home.

In next letter will record plight of despised storekeeper.

INO AMSURA.

Pennsylvania Decapod, Type 11s

PENNSYLVANIA DECAPOD SHOWS HIGH ECONOMY

Report of Tests Comparing 11s, Hand and Stoker Fired, with the Performance of the L1s Mikado

IN 1916 the Pennsylvania Railroad built a locomotive of the 2-10-0 type with cylinders working at a maximum cut-off of 50 per cent. This locomotive with minor alterations was adopted for heavy freight service and a large number of the class 11s, as this type is designated, are now in use. The design of this locomotive was described in the *Railway Mechanical Engineer* for July, 1917, page 370. Details of the performance as disclosed by the results of test

For the purpose of developing a practical means of obtaining the economies above outlined, a locomotive was built and placed on the locomotive testing plant before going into road service, as the innovations in design made it especially desirable to have complete test results before building additional ones. As a result of the tests and the general performance of the locomotive in service, certain alterations were found advisable.

Fig. 1. Rate of Combustion and Boiler Efficiency

plant trials, are now available in Bulletin No. 31 (copyright 1919 by the Pennsylvania Railroad), from which the information in this article has been secured.

In discussing the considerations which led to the development of the 11s the bulletin points out that many locomotives, in helping service especially, are worked almost continuously with a cut-off near the end of the stroke. If they were designed so as to work at but 50 per cent cut-off when in full gear, without a sacrifice of drawbar pull, there would be gained the difference between the coal and water rates at full stroke cut-off and those at half stroke, or a saving of approximately 25 per cent. The locomotive needed at a number of points on the Pennsylvania was one having a drawbar pull 25 per cent greater than that of the class L1s, Mikado type, or one having a pull of about 75,000 lb. at 10 miles an hour. A study of such a locomotive, with a limited or restricted cut-off in a two-cylinder arrangement, indicated that the desired result could be obtained with a half stroke maximum cut-off, giving a turning moment diagram very similar to that of locomotives cutting off at full stroke.

Description of the Locomotive

Locomotive No. 790, as finally arranged for these tests, is of the Decapod or 2-10-0 type with two cylinders 30½ in. in diameter and having a stroke of 32 in. The boiler pressure is 250 lb. per sq. in. and the maximum cut-off is limited to approximately 50 per cent of the stroke. In many particulars the design follows closely that of the class L1s, Mikado type, which preceded it.

The table following shows how the locomotive compares with the class L1s in certain leading dimensions. The total heating surface is about 12 per cent larger than that of the class L1s, and the total weight about 16 per cent greater. The grate areas of the two locomotives are alike.

GENERAL DIMENSIONS OF LOCOMOTIVES OF THE 11s AND L1s CLASSES

	Class 11s 790	Class L1s 1,752	Increase of 11s over L1s, per cent
Weight in working order, total pounds..	371,800	320,700	15.9
Weight on drivers, working order, pounds	342,050	240,200	42.4
Driving wheels, diameter, inches.....	62	62	...
Cylinders (simple), inches.....	30½ by 32	27 by 30	37.6 Vol.
Heating surface, tubes (water side), sq. ft.	4,043.94	3,715.71	8.8
Heating surface, firebox (including arch tubes), sq. ft.	290.20	301.51	3.8 Dec.
Heating surface, superheater (fireside), sq. ft.	1,478.91	1,171.63*	26.2
Heating surface, total (based on water-side of tubes), includ. superh., sq. ft.	5,810.25	5,188.85	12.0
Heating surface, total (based on fireside of tubes), including superheater, sq. ft.	5,423.12	4,847.72	11.9
Grate area, sq. ft.....	70.0	70.0	0.0
Boiler pressure, pounds per square inch.	250.0	205.0	22.0
Valves	12-in. piston	12-in. piston	...
Valve motion, type.....	Walschaert	Walschaert	...
Firebox, type	wide, Belpaire	wide, Belpaire	...
Tubes, number	244	237	...
Tubes (outside diameter), inches.....	2.25	2.25	...
Flues (for superheater), number.....	48	40	...
Flues (outside diameter), inches.....	5.5	5.5	...
Tubes and flues, length, inches.....	228.32	228.51	...

*This is the heating surface of the 17-ft. superheater. The standard length superheater for the L1s is now the same as for the 11s or 18 ft., with a heating surface of 1,234.65 sq. ft., but the 17-ft. superheater was used in the L1s tests herein reported. The 11s superheater surface is about 20 per cent larger than that of the 18-ft. superheater for the L1s.

Tractive Force

In calculating the maximum tractive force of this locomotive the mean effective pressure reaching the drawbar

cannot be taken as the usual 85 per cent of the boiler pressure, because of the limitation of the cut-off. Indicator diagrams, made in road service, at starting in full gear, show an average m.e.p. of about 75 per cent of the rated 250 lb. boiler pressure, or somewhat more, according to the time in which the first revolution is made, controlling the amount of steam passing through the auxiliary port. With 30½-in. by 32-in. cylinders, the calculated maximum tractive force may, therefore, be assumed to be that based on 75 per cent of the boiler pressure, or 90,000 lb. The ratio of weight on drivers to this calculated tractive force is 3.8. After the first few revolutions, it is expected that the draw-bar pull will fall to that due to about 70 per cent of boiler pressure as m.e.p., or 84,000 lb., with a ratio of 4.07.

Boiler

The boiler is similar in design to the boiler of the class Ls, but the boiler tube surface and superheating surface are both somewhat larger. The superheater has 48 elements, where the class Ls has 40. The length of tubes and superheater flues, 19 ft., is the same as in the class Ls locomotive.

Fig. 2. Typical Indicator Diagrams

The details of the cylinders, ports and valves were described in the article referred to above. It may be well to mention that the valves have a travel of six inches in full gear and to obtain a short cut-off with this long travel, it was necessary to make the steam lap two inches. Full gear cut-off with six-inch valve travel is at 50 per cent of the stroke; however, to distinguish tests in full gear cut-off at slow speed, with allowance for steam passing through the auxiliary ports, such tests are marked 55 per cent cut-off as determined from the indicator diagrams. The lead of the valves in full gear is 3/16 in. The exhaust lap is 1/8 in.

Auxiliary ports are cut in the valve cages, 1¼ in. in advance of each of the main steam ports, and are intended to assist in starting; however, they are in action at all times when the locomotive is moving under steam. The ports are 1/8 in. by 1½ in., with a steam lap of 1/4 in., and are located at each end of each cylinder at the bottom of the valve cage or bushing, making four ports in all.

Coal

Over 70 tests were made to develop the performance of the locomotive, and of these tests 39 were fired by hand with run-of-mine coal. In the 1917 tests Jamison coal was used, but on account of the difficulty in getting this coal in 1918, the tests were made with Crows Nest coal. These two coals are from the same region and vein and are alike in many respects. This is further illustrated by the average analyses,

given in the following table, which have been made from all of the coal used in the hand-fired tests:

	Jamison coal 1917	Crows Nest coal 1918
Fixed carbon, percentage.....	56.21	56.80
Volatile combustible, percentage.....	31.34	29.68
Ash, percentage.....	11.67	12.26
Moisture, percentage.....	0.97	1.25
Total.....	100.19	99.99
Sulphur, percentage.....	2.15	1.41
B. t. u. per lb. dry.....	13,429	13,420
B. t. u. per lb. combustible.....	15,221	15,324

Tests with Hand Firing

Boiler Performance

Pressures and Temperatures.—An average boiler pressure within about four pounds of the rated pressure of 250 lb.

Fig. 3. Coal to Engines and Indicated Horsepower

per square inch, was maintained in all of these tests. The maximum pressure drop, or loss between the boiler and branch pipe was 18 lb., this drop being at a rate of steam flow of 58,000 lb. per hour. The exhaust steam pressure

Fig. 4. Indicated Horse Power and Coal (Average for All Cut-offs)

shows a maximum of 16.3 lb. per square inch. Even with a boiler pressure of 250 lb., the maximum superheat temperature was 282.8 deg., which is nearly as high as has been obtained on any locomotive on the test plant, all of which have had a boiler pressure at or below 205 lb.

Combustion, Draft and Temperature.—In general, the

draft or vacuum was higher in the IIs than in the LIs at all rates of evaporation. This is to be expected, as the exhaust nozzle area was 35.8 sq. in. for the IIs and 38.3 sq. in. for the LIs. Though not greatly different, the smokebox temperatures are somewhat higher than in tests of the LIs.

The feedwater temperature was between 37.3 and 64.9 deg. The firing was all by hand as the locomotive was not at this time equipped with a stoker. The rate of firing reached 189 lb. an hour per square foot of grate, and at this rate the evaporation per square foot of heating surface was

Fig. 5. Indicated Horse Power and Steam (Average for all Cut-offs)

10.3. The maximum rate of firing, in pounds per hour, was 13,226.

Evaporation.—The evaporation of this boiler appears to be less than was obtained from the smaller LIs boiler, but when the higher pressure and superheat of the IIs are considered, the maximum equivalent evaporation of the IIs is considerably above that of the LIs. The equivalent evaporation per pound of coal is illustrated by Fig. 15. The evaporation per pound of coal and the boiler efficiency results are about the same as were obtained in 1917 (see Fig. 1.). The equivalent evaporation per square foot of heating surface for the IIs reached a maximum of 14.7 lb. per hour.

Superheat.—The IIs shows a maximum superheat of about

Fig. 6. Water Rates at All Cut-offs, Class IIs

280 deg. and at a rate of firing of 11,000 lb. per hour the superheat is about 15 per cent higher than for the LIs when equipped with a superheater of the same length as in the IIs, or 18 ft. When these two superheater surfaces are compared, that of the IIs is larger by about 20 per cent, on account of the larger number of elements.

The normal saturated steam temperature for the IIs is 406 deg. and for the LIs, with a boiler pressure of 205 lb., it is 389.5 deg. It would appear to be more difficult then to superheat the steam from the IIs boiler on account of its

higher initial temperature, but notwithstanding this, a higher maximum superheat was obtained, although it is somewhat lower over part of the range.

The water heating surface of the IIs boiler is 8.8 per cent, the total heating surface 12.0 per cent, and the fire area through the tubes 7 per cent greater than the corresponding parts of the class LIs. For these reasons it was expected that an evaporation somewhat higher than in the case of the LIs class, over 59,000 actual, or 77,000 equivalent pounds per hour, would be possible when using an exhaust nozzle seven inches in diameter, or the same diameter as was used on the LIs.

With a seven-inch diameter exhaust nozzle (1917 tests), an evaporation of about 53,600 actual, or 72,500 equivalent pounds per hour was obtained. This was not considered sufficient, in view of the performance of the class LIs, and many changes were made in the arrangement of the diaphragm in the smokebox and different forms of stack were tried. Finally, by reducing the nozzle diameter to 6 3/4 in., an evaporation of 59,300 actual, or 81,900 equivalent pounds was obtained.

The tests of the 1918 series, beginning with 5401 and ending with 5416, were made with a seven-inch exhaust nozzle, and it was used again in tests 5431 to 5438. Test 5412 at 80-55-F, evaporating 51,280 lb. per hour, proved to be the limit with this nozzle and smokebox arrangement. It was found, after test 5416, that cinders were accumulating in the front end, and to overcome this the exhaust nozzle was reduced to 6 3/4 in. and a deflector plate, eight inches wide, put on the edge of the table plate in front of the nozzle. This deflector made the gas passage, at the smallest area, the

Fig. 7. Water Rates at All Cut-offs, Class LIs

same proportion of the fire area of tubes as on the classes LIs and K4s, where it is 68 per cent.

Arranged in this way, the evaporation, in test 5443 was 58,300 lb., or an increase of about 14 per cent over the evaporation that could be obtained with the seven-inch nozzle without the deflector. When equipped with a stoker in later tests, an evaporation of 60,906 lb. was obtained, showing that the expected evaporation is easily possible with this locomotive.

While in the earlier tests a 6 3/4-in. exhaust nozzle was used, in the final tests it was found possible to use a 6 3/4-in. nozzle, but not a 7-in. The boiler conditions had been improved by the changes in the stack and front end, so that the 6 3/4-in. nozzle gave draft conditions as good and a

capacity as high as could be obtained with the 6¼-in. nozzle and the earlier arrangement of the front end.

Engine Performance

The engines of this locomotive, compared with long cut-off locomotives as to economy in coal and steam, have yielded expected results. The tests have shown that the restricting of the cut-off has had the desired effect in that, in full gear, where the bulk of the work is done, this locomotive operates much more economically than the Lls. This advantage, as expected, is reduced as the engines are cut back, but it is not until we have gone below the most economical cut-off for both locomotives that the Lls and IIs show the same economy at a given horsepower. This, moreover, is the case only at the lower horsepower (in short cut-offs at low speeds), that is, for but a small portion of the work done by the locomotive when in normal railroad service.

Indicator Diagrams and Action of Starting Ports.—Representative indicator diagrams are shown in Fig. 2. The principal point of interest in these diagrams is the action of the auxiliary starting port. It opens before the opening of the main port, having a lead of 1 15/16 in. in the tests

Fig. 8. Piston Speed and Water Rate

here recorded, as against 3/16 in. for the main port and, on the indicator diagrams, the effect caused thereby can scarcely be noticed. Considering the cards for full gear, there is no evidence that the auxiliary ports admit a sufficient amount of steam to hold up the admission line appreciably, after the cut-off of the main port. The testing plant conditions in starting are not the same as on the road, on account of there being little or no resistance to turning the locomotive wheels and no rolling load, in the form of the locomotive itself and the train.

Indicated Horsepower.—The test results in indicated horsepower are plotted on Fig. 3. The range of horsepower was between 766.6 and 3,486.1. The highest power was obtained at a speed of 140 r.p.m., which is equivalent to 25.3 m.p.h.

The superheated steam used per i.h.p. hour was between 14.9 and 21.6 lb. In 12 of the tests the steam used per i.h.p. hour was 16 lb. or less. On 16.6 lb. of steam per i.h.p. hour, an indicated horsepower of about 3,500 was developed.

Many tests show a coal consumption of between two and two and a half pounds per horsepower hour, while the maximum rate, neglecting test No. 5417 as abnormal, was less than three and a half pounds per i.h.p. hour. The curves as drawn for the class IIs, Figs. 4 and 5, show lower

results in steam and coal per unit of power than for the class Lls at any power.

The indicated horsepower at 7.4 miles per hour, in full gear, is 1,743.7. With the Lls at the same speed in full gear it is about 1,220. This is an increase in power over the Lls of about 43 per cent. The maximum horsepower was obtained at 25 miles per hour and 45 per cent cut-off; this was 3,486. With the Lls the maximum power at this speed was 2,755, or about 80 per cent of that of the IIs. The Lls has developed on the test plant 2,954 hp. at a speed of 29 m.p.h.

Steam Rate Curves.—In Figs. 6 and 7 curves are plotted

Fig. 9. Indicated Horsepower and Efficiency of Engines

showing the whole range of weight of steam per indicated horsepower hour for the locomotives, classes IIs and Lls. Considering the speed of 40 revolutions per minute or 7 m.p.h., and full gear, it is found from these diagrams that the IIs developed 1,740 i.h.p. and used about 19.5 lb. of steam per horsepower hour, while the Lls developed 1,230 hp. and used 31.5 lb. of steam per horsepower hour. At a speed of 120 r.p.m., 22.1 m.p.h., and at a cut-off of 50 per cent, for the IIs the horsepower is about 3,280, while for

Fig. 10. Drawbar Pull of the I1s and L1s at Various Speeds

the Lls it is about 2,050, and the steam per indicated horsepower for the IIs is 16.8, while for the Lls it is 18.0. In this latter case little or no saving would be expected and the difference may be attributed to difference in quality (pressure and superheat) of the steam. In full gear, at low speed, the reduction in the steam per indicated horsepower by the IIs over the Lls is, as above indicated, approximately 38 per cent.

Piston Speed and Water Rates.—The water rate of the locomotive improves to a certain extent with an increase in

piston speed, and this is shown by the plotted results in Fig. 8. The weight of steam per indicated horsepower for the IIs locomotive is in a separate zone from that of the Lls, and less steam is used when the two locomotives are tested under like conditions.

On account of the small exhaust nozzle and higher boiler pressure, the back pressure was in general somewhat greater than for the Lls.

Thermal Efficiency of Engines.—The thermal efficiency of the engines alone, referred to indicated horsepower, calculated according to the method of the A.S.M.E., is shown in Fig. 9. This efficiency is the proportion of the total heat consumed which is converted into work in the cylinders. The heat considered is that in the steam in the branch pipe,

ing moment in the case of the class IIs, cutting off at half stroke, forms nearly as smooth a curve as for the class Lls, cutting off at nearly full stroke, and therefore that the advantages of a favorable cut-off are obtained in this locomotive without introducing high peaks in the curve or any unusual tendency toward slipping of the driving wheels.

Machine Friction.—The machine efficiency of this locomotive is plotted in Fig. 13. The highest efficiency is 91.7 per cent. At the lowest speed of the tests, 7.4 m.p.h. in full gear, it was 85.6 per cent. In tests of the class Lls the machine efficiency was in some cases as high as 95 per cent and at 7 m.p.h., in full gear, it was 94 per cent. The thermal efficiency of the locomotive (proportion of total heat consumed converted into work at the drawbar) is shown in

Fig. 11. Tractive Effort Curves, Full Gear, Class IIs

Fig. 12. Tractive Effort Curves, Full Gear, Class LIs

above an ideal feedwater temperature which is assumed to be that as observed of the steam in the exhaust pipe. These efficiency results show that there is much improvement in the IIs over the class Lls. The efficiencies of the locomotive are between 10 and 16 per cent, while those of the class Lls are between 10 and 14 per cent.

Locomotive Performance

The dynamometer horsepower shows increases and economies closely following those for indicated horsepower. Many tests have a coal rate of 2½ lb. (see Fig. 16) and a steam rate of less than 18 lb. The minimum rate was 16.8 lb. of steam per d.h.p. hour. Both the coal and water rates are below those of the class Lls for all dynamometer horsepower.

The drawbar pulls obtained upon the testing plant are shown in Fig. 10. To be 25 per cent greater than the pull of the Lls at 40 r.p.m., the IIs should have a pull or about 75,000 lb., and this pull was considerably exceeded. In the tests with 30-in. cylinders at a speed of 40 r.p.m. or 7½ m.p.h., the drawbar pull on the test plant was 68,000 lb., and later on the road about 76,000 lb. With the new 30½-in. cylinders, on the test plant the pull at this speed was 76,000 lb.

Cylinder Tractive Force.—Comparative turning moment or cylinder tractive force curves for the class IIs Decapod type, and the class Lls Mikado type, are shown in Figs. 11 and 12. It will be seen from these diagrams that the turn-

ing moment in the case of the class IIs developed a maximum efficiency of 8.1 per cent, while the highest attained by the Lls was 7.0 per cent.

Tests with Duplex Stoker

Following the hand-fired tests locomotive No. 790 was equipped with a Duplex stoker. It was then returned to the test plant and the tests continued with the stoker in use. The stoker was piped so that its exhaust steam could be turned into the base of the elevator screws to dampen the coal, the claim being made that this will reduce the smoke.

For the remaining tests the stoker was used without any hand firing and the test conditions duplicated as nearly as possible the hand-fired tests. Some of the stoker-fired tests were made to obtain the steam consumption of the locomotive only and were run for too short a time for reliable coal data. These have not been plotted on the diagrams.

The stoker speed at first was found to be too low, not over 40 strokes per minute, and in order to increase the speed changes were made in the steam ports of the stoker cylinder by enlarging and extending them. The exhaust pipe from the stoker engine was also enlarged to two inches. After these changes the stoker could be run at 48 strokes per minute, and it was possible to fire all of the coal that could be burned. The same kind of coal was used for the stoker tests as for the hand-fired tests, namely, Crows Nest run-of-mine.

The exhaust steam from the stoker cylinder was led to a condenser and the condensed steam weighed in the first

nine tests. From these records it was found that about 1/4 lb. of steam was used per double stroke or revolution of the stoker, and for the remaining tests the stoker exhausted to the atmosphere and the steam used was calculated. The steam used by the stoker steam jets could not be measured directly and was calculated by the Grashof formula.

Coal.—The average analyses of the Crows Nest coal used for the hand-fired and stoker tests, are shown in the following table and indicate a very small difference.

	Hand fired	Stoker fired
Fixed carbon, percentage.....	56.80	58.68
Volatile combustible, percentage.....	29.68	29.92
Ash, percentage.....	12.26	10.18
Moisture, percentage.....	1.25	1.23
Total.....	99.99	100.01
Sulphur, percentage.....	1.41	1.54
B.t.u. per lb. dry.....	13,420	14,130
B.t.u. per lb. combustible.....	15,324	15,662

Results of Tests.—The results of the stoker-fired tests are plotted in Figs. 15 and 16, and on these diagrams the hand-fired test results, made immediately before the application of the stoker, are shown for comparison.

Maximum Capacity with Stoker.—It is evident from the tests that the evaporation and rates of firing are but little more than can be obtained by hand firing, so that the

Fig. 13. Machine Efficiency

capacity of the locomotive was not increased by the stoker, but of course the maximum evaporation is obtained with much less exertion on the part of the fireman, and also it is evident that the maximum evaporation can be sustained for a longer time with the stoker.

It was found that the boiler could not be forced much beyond an evaporation of 60,000 lb. per hour, indicating this to be the boiler limit for both hand and stoker firing.

Coal Economy with Stoker.—A further analysis of the stoker test results shows that hand firing is superior in evaporation per pound of coal at low rates of firing, but that this advantage decreases until, when the boiler is evaporating its maximum weight of water the stoker firing is no less economical than the expert hand firing. The advantage shown for hand firing is about 19 per cent when firing 40 lb. of coal per square foot of grate per hour, and decreases to nothing when firing 180 lb. per square foot. (See Fig. 15.) There is practically no difference in the

superheat of the steam with or without the stoker. The range of the superheat is between 130 and 285 deg.

Stoker Exhaust to Conveyor.—The stoker engine ordinarily exhausts to the atmosphere, but there is also a pipe connection to the base of the elevator screws, and when this was used the coal was dampened by the exhaust steam. With this connection in use in test No. 5470 there was a marked reduction in the smoke and also a smaller coal consumption, but as there was only one test made under these conditions no very definite conclusions can be drawn, although the indications are that there is some advantage to be gained by its use. The results obtained with it, compared with

Fig. 14. Thermal Efficiency of the Locomotive

both hand and stoker-fired tests without it, are shown in the following table:

Test No.	Test designation	STOKER-FIRED TESTS			Exhaust of stoker engine to—
		Coal fired, lb. per hour	Equivalent evaporation per lb. dry coal	Smoke percentage	
5,470.....	120-30-F	5,505	9.1	15.6	Conveyor
5,447.....	120-30-F	5,783	8.7	27.0	Atmosphere
5,449.....	120-30-F	6,019	8.3	22.8	Atmosphere
5,456.....	120-30-F	6,304	7.8	32.4	Atmosphere
		HAND-FIRED TESTS			
5,432.....	120-30-F	4,641	10.3	7.2
5,428.....	120-30-F	4,720	9.8	8.2
5,441.....	120-30-F	4,943	9.7	18.8

Steam Used by Stoker.—The estimated weight of steam used by the stoker ranged between 393 and 1,629 lb. per hour, and was about two per cent of the steam generated by the boiler. There was more hooking or leveling of the fire in hand firing than when the stoker was used. This would indicate that the stoker maintained a more nearly level fire than could be obtained by hand firing. The number of times the grates were shaken was practically the same for either hand or stoker firing.

Conclusions

With this boiler, carrying a steam pressure of 250 lb. per sq. in., no difficulty was found in superheating the steam to a high temperature. The water and superheating surfaces are larger than those of the class L1s locomotive and a greater equivalent evaporation was obtained.

The engines of this locomotive compared with long cut-off locomotives as to economy in coal and steam, have met expectations. The tests have shown that the restricting of the cut-off has had the desired effect in that, in full gear, where the bulk of the work is done, this locomotive operates much more economically than the L1s. This advantage, as expected, is reduced as the engines are cut back, but it is not until below the most economical cut-off for both locomotives that the two classes of locomotives show the same economy.

In the results of the tests which show power and steam used, the action of the stoker need not be considered, and it was found in many tests that the steam rate per i.h.p. hour was

16 lb. or less. At a rate of only 16.8 lb. of steam per hour an indicated horsepower of over 3,500 was developed. The saving in steam per indicated horsepower over the Lls is very evident and, except at low horsepower at low speed, it is not possible to operate the Lls at as good advantage as the IIs, and in full gear at low speed, the reduction in steam per indicated horsepower, over the Lls is 38 per cent.

The maximum evaporation was obtained with the stoker with very little exertion on the part of the fireman. The stoker fired a fairly level fire, and could be operated under

ANATOLE MALLET

Anatole Mallet, the inventor of the compound locomotive which bears his name, died in Nice, France, in October, 1919. Mr. Mallet was born in 1837 at Carouge and was graduated in 1858 from the Central School of Arts and Manufactures in Paris. He was engaged in civil engineering work for several years, first with the Bureau of Direction of the General Company of Railroad Materials in France and later on the Suez Canal. In 1864 he was engineer for a company which undertook dredging operations in Italy. His first work in mechanical engineering was done in 1867, when he devoted his attention to double expansion steam engines. The first application of this system was made in 1876 on a two-cylinder compound which operated on the line from Bayonne to Biarritz. This design effected a saving of 20 per cent in fuel over the standard types and placed the inventor in the foremost ranks of locomotive designers.

The great success of the compound locomotive led to a material increase in the size of the units and to the development of three and four-cylinder compound locomotives. It became evident that the limit of size of locomotives of rigid construction, especially on lines with sharp curves, would soon be reached. In order to permit of the use of large motive power units on lines with sharp curves and light track, Mr. Mallet designed the articulated type of locomotive which was first introduced in this country on the Baltimore & Ohio and has since been adapted to use on American roads with such great success.

Among the honors conferred upon Mr. Mallet were the Schneider prize, awarded to him by the French Society of Civil Engineers in 1902, and the annual prizes of the society in 1909 and 1911. He was made a Knight of the Legion of Honor in 1885 and promoted to officer in 1905. The Institute of Mechanical Engineers of London awarded him a gold medal in 1915. He was a member of the Society of Civil Engineers of France, the Society for the Encouragement of National Industry of France, and the Franklin Institute of Philadelphia.

In addition to carrying on his engineering work, Mr. Mallet took active part in the work of the French Society of Civil Engineers from 1880 to within a few months of his death. He was editor of the Chronicle of the Bulletin of the Society, for which he wrote numerous technical notes and important memoirs. The last of these, treating of the practical evolution of the steam engine, earned for him the honors conferred by the society.

* * *

Fig. 15. Evaporation per Pound of Coal, Hand and Stoker Firing

all conditions in a satisfactory manner without any hand firing.

Except at the highest rates of firing, the stoker is wasteful in the use of coal, but appears to be no more wasteful than other stokers, and in addition has advantages over the other stokers tested, in ease of operation and in the absence of obstructions at the fire door and on the grates.

The estimated weight of steam used by the stoker was about two per cent of the steam generated by the boiler. The advantage shown for hand firing over the stoker firing in

Fig. 16. Indicated Horsepower and Coal, Hand and Stoker Firing

equivalent evaporation per pound of coal is about 19 per cent when firing 40 lb. of coal per square foot of grate per hour, and decreases to nothing when firing 180 lb. per sq. ft.

With the stoker it is to be supposed that a greater number of firemen could obtain the full capacity of the locomotive than would be the case with hand firing, because of the ease of handling the stoker. Such considerations, combined with those of economy or capacity as shown by tests, in the case of locomotives of this class, must govern in deciding whether a stoker is necessary.

LABOR'S SHARE OF RAILROAD EARNINGS.—Statistics of earnings and expenses of the railways in 1919 show that of the average earnings of a month of 30 days, labor received in wages the earnings of 17½ days of each month, fuel required the earnings of three days, material and supplies five days, taxes, etc., one and one half days, leaving the earnings of three days for net operating income.

Cars with Cans of Milk Remaining Undelivered Because of the French Railway Strike

WORK OF THE MECHANICAL DEPARTMENT IN 1919

Railroad Administration Report Summarizes the Activities of the Division of Operation

THE annual report of the director general of railroads for the year 1919 contains an interesting summary of the work of the mechanical department. An extract from the report of W. T. Tyler, director of the Division of Operation, follows:

In general, the work of the mechanical department has been similar to that performed during 1918, except that it has been more extensive. The organization has not been substantially changed, but has been somewhat increased over that at the close of 1918. At present it consists of Frank McManamy, assistant director, in charge of the department; George N. DeGuire, general supervisor of equipment, and George E. Dougherty, assistant general supervisor of equipment, whose duties are to supervise in a general way the condition of and repairs to locomotives and cars in railroad shops and to check up shop practices and expenditures with a view to promoting both efficiency and economy in the maintenance and operation of equipment; F. P. Pfahler, chief mechanical engineer, whose duties are to supervise the design and construction of new locomotives and cars, pass on disputed points in connection therewith, check bills for alterations or changes, handle locomotive assignments, and such other duties as may be assigned to him; J. J. Tatum, general supervisor of car repairs, whose duties are to supervise the general condition of and repairs to freight and passenger cars, see that repairs are promptly and efficiently made, and arrange for the distribution of cars as between different shops, so that the greatest efficiency may be obtained; J. R. Jackson, mechanical engineer, who in addition to the usual duties of a mechanical engineer is also in direct charge of the investigation of new inventions and appliances. In addition there is a field force of 24 men, whose duties are to make special investigations, check up methods of handling and repairing locomotives and cars, promote shop efficiency and such other special work as may be assigned; and the necessary office force consisting of 52 persons who perform the usual duties in connection with the handling of correspondence and records.

The field force has been a potent factor in promoting efficiency and controlling the cost of maintenance of equipment, and the part performed by the force in the matter of assisting the work of both the locomotive and car departments on the different railroads and the consolidation of the work as between different railroads has been of real value.

No additional orders for new locomotives or cars have been placed during the year 1919, but work has been pushed on the completion and assignment of the cars and locomotives built to standardized designs which were ordered during the year 1918.

Maintenance of Equipment

During 1919 the railroads in federal operation operated 65,100 locomotives, 54,193 passenger train cars, and an average of 2,430,719 revenue freight cars.

There has been no shortage of locomotives during 1919; in fact, the increased efficiency in locomotive maintenance and operation effected by the more general use of locomotive repair facilities and by increased efficiency in handling at terminal points has resulted in a surplus of locomotives during the entire year.

Owing to the increased capacity of the locomotive repair shops there were on January 1, 1919, 1,384 locomotives in good condition in storage. On April 1 this number had increased materially. This early period of 1919 was one of light business, which rapidly changed to brisk traffic about the middle of the year.

During the period from November 1, 1918, to September 30, 1919, 43,608 locomotives were given classified repairs and 298,183 locomotives were given repairs requiring over 24 hours. Ordinarily running repairs which are required after each trip and which consume less than 24 hours are not included.

The classified repairs were in accordance with the United States standard classification, which requires certain essential repairs to be made and locomotives placed in condition to perform a specified term of service before they can receive credit for class repairs.

On January 1, 1919, there were 138,722 freight cars, which is 5.8 per cent of the total revenue cars in service at that time, in bad order. This number decreased to such an extent that on March 1, 1919, only 127,336, or 5.2 per cent, cars were in bad order.

The adjournment of Congress on March 4, 1919, without providing the appropriation requested by the Railroad

Administration made it necessary to exercise the most rigid economy in maintenance of equipment expenditures; therefore car-repair forces were reduced on practically all railroads under federal control. This reduction in car-repair

forces resulted in an increase in the number of bad-order cars. On June 20 instructions were issued to restore car-repair forces, but before this order could be made effective on all railroads the number of bad-order cars had still further increased. The strike of the shopmen on August 1, which, although unauthorized by the employees' organizations, resulted in large numbers of car repairers leaving their work for a period of approximately 10 days, still further increased the number of bad-order cars, until on August 16 there were 228,549 bad-order cars, which is 9.2 per cent of the total number of revenue cars.

Since that time, however, the work of conditioning freight cars has been vigorously pushed until at present there are but 127,182, or 5.1 per cent revenue cars in bad order that will be repaired. This does not include 19,300 cars set aside under the provisions of Circular 20, issued by the Division of Operation, which are in effect condemned cars which will not be repaired by the administration and are being held because the owning corporations have not agreed to their dismantling on the basis given in the master car builders' rules.

During the period from November 1, 1918, to September 27, 1919, a total of 21,080,127 freight-train cars were repaired in the shops of railroads in federal operation. During the same period 14,119 cars were repaired in contract shops, and 20 new contracts were made covering 17,600 cars to be repaired by such concerns. This illustrates the diligent efforts which were made to condition freight cars to meet the demands of the traffic.

During the period from November 1, 1918, to September 1, 1919, 417,320 passenger-train cars were given either running or classified repairs.

Maintenance of equipment, labor disputes and the national agreement; safety appliances and standard practices and vocational training of railroad employees are some of the subjects discussed

Immediately following the signing of the armistice instructions were issued to eliminate where practicable the overtime worked in repair shops, and employees in all shops and car-repair plants were reduced to the regular day's work of eight hours. While this of necessity resulted in a decrease in the number of cars repaired, it was only fair to employees who for many months had been faithfully working whatever hours were required of them by the administration, and the restoration of the established eight-hour day was a deserved recognition of the co-operation and faithful service rendered.

The difficulty in securing necessary material for repairs to both locomotives and cars continued for a considerable portion of 1919. Where shortages of material were found to be delaying equipment, necessary action was taken to obtain either from the manufacturers or from some other railroad the material needed to complete the work and avoid delay to equipment. This has been one of the most valuable activities of the central administration.

The work of modernizing existing equipment has not been overlooked, and in line with plans which were partially completed when the roads were taken under federal control 1,123 locomotives have been equipped with superheater since November 1, 1918, preference in all cases being given to the heavier power.

Other devices, such as stokers, power-reverse gears, power-grate shakers and similar appliances which make for efficiency and economy in locomotive operation, have been applied to the extent that the conditions under which the railroads are operated would permit.

The work of applying headlights to locomotives in accordance with the orders of the Interstate Commerce Commission has been diligently followed with the result that substantial progress has been made, and the indications all point to the fact that this work will be completed well within the time provided.

Control of Maintenance of Equipment Expenditures

From the beginning the mechanical department has diligently endeavored to maintain the equipment without any idea that economies should or could be realized by reducing maintenance which the equipment ought to receive. With this thought in mind, we began immediately after the roads were placed under federal control to check locomotive shop output and roundhouse and shop costs, so that all unnecessary expenditures might be eliminated and greater efficiency in shop and roundhouse operation obtained. Where improper practices were found to exist, action was taken through the regional directors to have more efficient methods adopted.

In order that expenditures for maintenance of equipment might be measurably controlled, federal managers were required to prepare and submit on suitable forms information regarding maintenance of equipment during the test period, during the seven years prior to the test period, as well as during the calendar year of 1918. This information was collected on the basis of the miles of roads operated, the units of equipment, and the locomotive and car miles, together with averages showing the cost of locomotive repairs separately on the basis of miles run, tractive power miles, and per locomotive owned.

Freight-car repairs were reported on the basis of 10,000 freight-car miles and freight cars owned, and the passenger-train car repairs were reported on the same basis.

From these reports studies of the maintenance of equipment costs were made and furnished to the regional directors, to keep them in touch with the actual conditions and aid them in the control of maintenance of equipment expenses.

In this work we have constantly kept before us the thought that the ability of the railroads to move present and prospective business was the first consideration, and after this requirement had been fully met reductions in maintenance expenditures which could properly be made should be made

on railroads which were clearly overexpended in the matter of maintenance of equipment in comparison with the test period, but in no case has the fact that a railroad has been overexpended for maintenance of equipment been permitted to reduce maintenance to a point where it would interfere with the handling of traffic.

Analyzing and tabulating the information received from the different railroads in connection with the maintenance of equipment expenditures is going forward, so that all available data may be in shape for proper consideration when needed. This also includes the establishment of equation factors for increased cost of labor and material to enable comparisons to be made as between the test period and the period of federal control.

Damage to Cars in Yards and in Trains

During the first year of federal control it was noted that the number of freight cars damaged in yards and in trains was excessive. A careful study was made to locate the cause, and it was decided that the number of cars so damaged could be materially reduced by more careful inspection and maintenance of hand-brake equipment, and by more careful supervision over switching in yards and the operation of trains.

A comparison of the last 7 months of 1918 with the first 10 months of 1919 will show the effect of the work which was done to reduce this damage. We are able to show this information for only 7 months of 1918 because prior to federal operation such information was not generally kept, and it was not until June, 1919, that reports were obtainable from all railroads.

During the 7 months for which this information was available in 1918 there were 179,145 cars damaged in yards and 401,670 damaged in trains, a total of 580,815 cars. During the period from January to October, inclusive, 1919, there were 179,921 cars damaged in yards and 335,798 damaged in trains, a total of 515,719 damaged, which is a decrease over the previous year of 37 per cent.

The average cost per month to repair the cars damaged in 1918 was \$1,779,240, which was reduced to \$1,366,555 in 1919, or at the rate of an annual saving of \$4,952,225.

Reducing the damage to equipment also reduces the damage to lading and permits the cars to remain in service. The reduction in freight claims and the value of cars in service can only be estimated, and therefore are not included in the above saving.

It would be exceedingly profitable for the railroads, after their return to private control, to continue a careful check of the damage to cars in yards and in trains and to establish a closer supervision over switching and train handling.

Committee on Standards

The present committee on standards was created as of July 1, 1918, for the purpose of carrying forward and completing the work of the original committee which designed the locomotives and cars, and which on account of other important duties of many of the members of that committee could not be continued.

In addition to completing the work started by the original committee, this committee has been called on to pass on various devices and methods used on locomotives and cars, as well as methods or devices intended to facilitate repairs and improve operation which were submitted under Circular 18. The committee has also been called on to act in an advisory capacity in the general activities of the mechanical department, including the preparation of specifications for new equipment, tests of material, and maintenance of equipment, as well as in connection with the use of numerous patented articles submitted for the use of the Railroad Administration.

The work of this committee in establishing standards for maintenance as well as for new equipment has been extremely valuable, and has made possible economies in the mainte-

nance of equipment and has reduced the delay to cars on repair tracks by providing a standard which could always be used without waiting to send to the home road for necessary materials to make repairs in kind. This committee has also been called on to investigate and pass on various methods or appliances essential for the promotion of safety in locomotive or train operation.

In order to handle the large number of inventions and devices to be used on or in connection with locomotives and cars, a committee on appliances, which is really a sub-committee of the committee on standards, was created. The work of this committee consists of investigating all inventions or devices submitted to the Railroad Administration in accordance with Circular 18 for use or for test; eliminating those that were clearly impracticable or unsuitable; making investigations of the results of the tests conducted by the various railroads of the different appliances, and submitting to the committee on standards those which appear to have sufficient merit to justify further investigation.

So that all matters submitted might have uniform treatment, the rules provided in Circular 18 have been strictly followed. These rules specifically provide that arrangements for tests of any device will not be made until an examination of the plans discloses the necessity or desirability of conducting such tests under service conditions. In case such test is to be made, the appliance must be furnished, installed, and operated without expense to the Railroad Administration. This work has covered a very wide field.

A classification of the invention files as of October 1, 1919, under 12 headings, shows a total of 1,160 devices and appliances. The investigations and reports on 225 of these devices have been completed, with the exception of 14 which were recommended for service tests. Reports on 245 devices are being delayed waiting for additional information from the inventor or railroads which have used the device.

Safety-Appliance Laws

The enforcement of the safety-appliance laws, which has been handled by the Railroad Administration since the railroads have been under federal control, has been under the direction of the mechanical department. During that period 13,295 specific violations have been filed by the Interstate Commerce Commission, all of which have been handled for correction.

As provided in General Order No. 46, reports of all violations were submitted to the mechanical department. The greatest number of such violations submitted was during the month of February, 1919, when 1,970 were submitted. Since that time the number of such violations has steadily decreased, only 731 having been filed in September, which indicates that the action taken has been effective.

During this period a number of matters which have been in dispute between individual railroads and the commission for several years have been satisfactorily settled. Among these is the matter of controlling the speed of freight trains on grades without the use of hand brakes. Failure to control trains with air brakes has resulted in numerous suits being filed by the Interstate Commerce Commission. For instance, this question was taken up with the Baltimore & Ohio Railroad in 1908, since which time it has repeatedly been before the courts without a definite conclusion.

It is believed that the matter has now been settled by conference and joint investigation arranged by the mechanical department between the Bureau of Safety of the Interstate Commerce Commission and the railroad officials. At this conference an agreement was reached as to a practical method of handling trains on the various grades as required by law, and instructions were issued by the Railroad Administration putting this arrangement into effect.

Similar conferences have been arranged in connection with other matters, and by working in close co-operation with the

representatives of the commission on these matters it is believed that much permanent good has been accomplished.

Action Taken to Promote Safety

In addition to the enforcement of the safety-appliance laws, an understanding was reached with the employees who in the past have been urging safety legislation, both state and national, that before such action was taken their demands would be presented to the Division of Operation for consideration, with a view to providing all necessary safety devices for the protection of the employees without the necessity of additional legislation, either state or national. Pursuant to this understanding, arrangements have been made by the mechanical department to equip locomotives with the following devices for the promotion of safety or efficiency, in addition to those required by federal laws:

Mechanical fire doors, lagging on steam pipes in cabs, standardization of location of air-brake cut-out valves in cabs; relocating air compressors so they will not obstruct the view of enginemen; applying handholds and suitable steps on sides of cabs; providing sanitary drinking water on locomotives; locating water glasses so they can be easily read by engineer and fireman, or applying second water glass if needed; applying electric marker and classification lamps; closing openings in cabs around boiler heads, injector pipes, reverse levers, etc.; providing cab heaters, equipping locomotives in cold climates with suitable cab curtains.

While these appliances are primarily in the interests of safety, they also promote efficiency and economy in locomotive operation.

Extension of Time for Applying Safety Appliances to Freight Cars

Due to the war and other causes, the application of safety appliances, as required by federal laws and orders of the Interstate Commerce Commission, had been delayed so that this important work could not possibly be completed within the time provided, although repeated extensions had been granted by the commission, the last one expiring on September 1, 1919.

Although it was suggested that an extension of time until January 1, 1921, be asked for, upon investigation made by the Railroad Administration, it was concluded that if vigorously pushed the necessary work could be completed in much less time. Therefore, a request was made to the Interstate Commerce Commission to extend this period, and after a hearing, at which the situation was presented to the commission, an extension was granted until March 1, 1920, to complete the work of equipping freight cars with safety appliances.

In order to force this work to a speedy conclusion instructions were issued that empty cars should not be accepted in interchange unless equipped with United States safety appliance standards.

This work is being closely followed, so that there may be no possibility of a further extension being needed. With the progress now being made it will be entirely practicable to withhold from service all cars not equipped prior to March 1, 1920.

Vocational Training for Railroad Employees

The plans for vocational training for railroad employees in connection with the Federal Board for Vocational Education, which were referred to in our 1918 report, have been completed, and all railroads under federal control have been authorized to co-operate with the Federal Board of Vocational Education in the establishment of training schools for apprentices.

The railroads have also been granted authority to require the attendance of apprentices at these schools not less than 208 hours per year, and to incur necessary expense to fit up suitable classrooms in which such classes may be held.

The Railroad Administration is also co-operating with the Federal Board for Vocational Education in the matter of training disabled soldiers and sailors for such work in the railway service as their physical condition will permit them to perform. Under the arrangements made with the Federal Board for Vocational Education, such men may be taken into railway shops and fitted for positions in mechanical work under a plan for special training and be paid by the railroad for their services approximately the wages of an apprentice. An additional allowance is made to such men by the Federal Board for Vocational Education, which will bring their pay somewhat higher than that of the average railway employee.

An understanding has also been reached with the employees' organizations that when these men have completed their course of training they may be employed as journeymen either in the shop where they have been trained or at any other point.

National Agreement

One of the inevitable results of federal operation of the railroads was the establishment of uniform rates of pay and working conditions for railway employees.

Under the arrangements in force when the railroads were taken over, each of the various railroad lines had its own shop rules or working agreement with the shopmen. This resulted in not only differences of rates but in working conditions on different railroads, which caused dissatisfaction and unrest among the employees and resulted in a movement of shopmen from road to road to take advantage of certain improved conditions. During the latter part of 1918 the shopmen requested consideration of a national agreement covering all railroads in federal operation, and such a proposition was submitted early in January, 1919. After consideration by various boards and committees, the matter was turned over to the mechanical department on September 11, and the negotiations with the shopmen's committee were completed on September 17; the agreement approved and signed by the director general and the executive officers of the employees' organizations on September 20, to become effective on October 20, 1919.

This agreement is in line with the labor policy of the Railroad Administration, and is an important step forward in dealing with the labor situation. It has already been demonstrated that putting the agreement into effect in a harmonious and co-operative manner has materially improved the labor situation by allaying the unrest among the shop employees which prevailed and insuring them uniform treatment and proper consideration, and improvement has already been noted in the operation of shops, engine houses and repair yards due to the more stable conditions brought about by this agreement.

An important fact developed in connection with the national agreement is that adequate provision was not being made to insure a future supply of mechanics by proper development of the apprenticeship system. At the ratio provided by the national agreement 64,159 apprentices could be employed, while a check of actual conditions shows that but 17,218 are employed. If we are to provide a future supply of skilled mechanics, more attention must be given to maintaining the full ratio of apprentices and giving them proper training.

Method of Handling Labor Disputes

During the year 163 labor disputes with shop crafts, some of them of an extremely difficult character, have been successfully handled by the mechanical department without

serious inconvenience to transportation and without the necessity of referring them to the Division of Labor. We have uniformly followed the policy of absolutely fair treatment of employees, exerting every reasonable means to correct any abuses found to exist and impressing upon all concerned the necessity of handling grievances in an orderly manner and in accordance with existing agreements.

In the cases where this failed and the employees stopped work, they have been plainly told that grievances would not be considered after the employees had left the service; therefore, the only way to obtain action was to return to work and present their grievances in an orderly manner.

The success of this policy has been proven by the fact that since the railroads have been in federal operation there has not been a single strike authorized by the executive officers of the various shopmen's organizations, and we have had their co-operation to the fullest extent to promote harmony and efficiency in shop work.

One of the provisions of the national agreement is that "prior to the assertion of grievances as herein provided and while questions of grievances are pending, there will neither be a shutdown by the employer nor a suspension of work by the employees." This is an important concession by both sides which, if fairly observed, will go far toward eliminating disputes between the railroads and their employees.

Distribution of Labor

The distribution of shop labor to meet the demands in different sections of the country under varying business conditions has received careful attention.

We have considered that each skilled mechanic trained in railroad work represents a certain definite investment which is lost to the railroads if, on account of a temporary period

of dull business, the man leaves railroad service to enter the employ of a private industry, because in many instances he never returns to railroad service. To avoid this loss of skilled workmen, as well as to provide employment during periods of dull business, arrangements have been made through the regional directors to provide employment within their region as far as practical for men who are laid off owing to dull business on the different railroads.

Where employment cannot be provided within their own region arrangements have been made to advise this office of all cases where there is a shortage or a surplus of skilled workmen when arrangements have been made for transfer. In this way we have been able to fill many vacancies as well as to provide employment for deserving workmen, and have thus retained to the Railroad Administration men who are skilled in mechanical work. In this we have had the close and sympathetic co-operation of the Railway Employees' Department of the American Federation of Labor, who furnish us with names of workmen seeking employment, and carefully follow up the cases where on their request workmen are sent to the different railroads to see that they accept the employment offered and for which they were furnished transportation.

It is believed that this work could be advantageously continued under private control and that it would be of decided benefit to both the railroad companies and to the workmen.

Activities of Field Men and the Saving Effectuated by Their Work

The work of the field forces has consisted of making special investigations of improper conditions reported, checking up conditions in shops, engine houses and repair yards for the purpose of promoting efficiency and economy in operation and handling labor matters that had not reached the stage

The director of the Division of Operation recommends the continuation of the administration's labor policy and standardization of the construction and repair of freight cars.

where they should be referred to the Division of Labor for settlement.

During the war the forces at practically all terminals had been built up to such an extent that they were out of proportion to the business handled. A check on the Erie Railroad in 1918 showed the need for a thorough investigation of shop and engine-house conditions on all railroads; therefore this work was extended and developed into a comprehensive system of reporting conditions of shop and engine-house operation monthly through the regional directors.

On account of the changed values due to increased labor and material costs, a comparison on a money basis was worthless; therefore all comparisons of shop and engine-house operation were made on a man-hour basis.

To illustrate the improvement in conditions, a check of 2,921 engine houses in January, 1919, showed an average of 30.58 man-hours per locomotive handled, while a check of the same engine houses in July, 1919, showed 25.77 man-hours per locomotive handled, or a decrease of 7,013,036 in the number of man-hours in handling approximately 54,000 locomotives. This represents a saving per month of \$4,263,541, which is at the rate of approximately \$50,000,000 per annum.

Other matters which have been investigated by the field forces include disputes between officials and the employees, losses due to good material finding its way into the scrap bins, shop practices and the efficient use of machine tools, storage of material to see that it is properly protected, condition of shops and shop grounds, condition of roundhouses, turntables, cinder pits and other terminal facilities to see that they were sufficient and were efficiently operated, checking up car-repair forces and facilities, and in many instances reorganizing forces at division points or on an entire railroad, seeing that shops and repair yards were properly supplied with material and tools so that the work could proceed without delay.

Distribution of Power

Through reports made each week by each railroad the mechanical department is kept informed as to the exact condition on each road with respect to motive power. This information enables us to promptly transfer locomotives from one road or section of the country to other roads or points where an actual or anticipated shortage of power develops to facilitate the movement of traffic.

In order to meet any contingency that might arise and avoid such congestion as existed in the latter part of 1917 and the beginning of 1918, 150 new Mikado and Santa Fe type locomotives were held in reserve in emergency pools at Albany, Buffalo, Cleveland, Columbus and Potomac yards. These locomotives were under the control of the mechanical department and were held for assignment to any road where, due to either adverse weather conditions or to increased volume of business, the need for additional power became apparent. From time to time locomotives as needed to tide over temporary emergencies were taken from these reserve pools and despatched to the roads or points where they were most needed. This reserve supply of locomotives was maintained until it became clearly apparent from the condition of power as well as from the demands that they would no longer be needed when the locomotives comprising the reserve were forwarded to the owning roads.

In addition to the locomotives in this reserve, 200 locomotives originally constructed for the Russian government are under the control of the administration, to be used as a power reserve, which can be promptly and easily transferred as the needs of the service demand.

The rapid development of the oil fields in the Southwest created an acute shortage of power on the roads traversing that territory, which was promptly met by the immediate

transfer of power from the East, care being taken to provide locomotives to meet the clearances and restricted bridge loadings in that territory.

In order to meet the increased demand for locomotives to move coal traffic a large number of locomotives were transferred to the coal-carrying roads in the Lake region during the early fall.

Approximately 750 locomotives have been constantly in service on other than owning lines. Their location has been changed from time to time to meet traffic conditions, which has enabled us to at all times furnish a sufficient supply of motive power to meet traffic conditions in the various sections of the country.

Since January 1, 1919, 2,307 locomotives have been given repairs in other than owning line shops.

A number of practices and methods established by the Railroad Administration should be permanently established and made standard because they are in the interest of economy, efficiency and uniformity.

Practices Which Should Be Continued and Made Standard

Among these is the standard classification of repairs to locomotives and tenders, because it forms a reasonably accurate basis of comparison of the work of the different shops and the cost of locomotive maintenance. It also promotes efficiency by establishing a certain definite standard for locomotive repairs, thus preventing the practice which is altogether too common of shopping locomotives at frequent intervals and doing only a portion of the work needed in order to increase the mileage between class repairs.

The standards for repairs to freight cars provided for in these circulars were established to avoid delays to freight cars when on other lines waiting for material to make repairs in kind.

On December 31, 1917, 52 per cent of the total number of freight cars were on their home lines, and at the present time less than 25 per cent of cars are on home lines, and it is extremely doubtful if this percentage will ever be materially increased, because no matter how diligent the efforts to send cars to home lines the first period of heavy business scatters them to all parts of the country, and it is months before they can again be returned to their home lines. For this reason the standardization not only of construction but of repair parts is a necessity if we are to properly maintain equipment at a reasonable cost.

In the interest of efficiency and economy individual standards of freight-car construction or repairs should never again be permitted, as there is not a logical argument that can be advanced in opposition to the standardization of freight cars on all roads.

For the above reasons the standards for repairs established by circulars 7 and 8 should be continued subject to necessary revision from time to time, and should be added to wherever it may be found practical to do so.

The inspection of stationary boilers by the railroads should be continued under their own supervision, thus insuring the very best possible character of inspection, and that inspections will be made at times when it will cause the least inconvenience.

This method of inspection will also promote efficiency and bring about uniformity in the different requirements, so that railroads operating through several states will not have a number of different standards of inspection for their stationary boilers.

Complete records of the standardized equipment constructed by the Railroad Administration, including drawings and prints, cost of maintenance as developed by special investigations or otherwise, and all other matters covered by this report or handled by the mechanical department, are available in our files for use when needed.

THE EFFECT OF MOLYBDENUM IN ALLOY STEELS

Increased Toughness and Wide Hardening Range Characterize Steels Containing This Element

IN the development of modern railroad equipment the excessive size of parts required to bear the high stresses is often a limiting factor. The use of alloy steels has been recognized as a possible method of overcoming these limitations, but the results secured with this material have not been wholly satisfactory.

The requirements of a steel for use in the running gear of a locomotive are (1) toughness and ability to resist sudden and repeated shocks, (2) ease of manipulation, to permit of handling it without installing special equipment. In addition, it is desirable that the steel have a high elastic limit and ultimate strength. The low carbon steels used in ordinary forgings meet the first requirements, but are deficient in strength. The majority of alloy steels have desirable physical properties, but require special care in working and cannot readily be handled in railroad shops. In view of these facts, it is interesting to note that steels alloyed with molybdenum, which seem to combine in an unusual degree the properties that have been found desirable for steels used in locomotives, are now being introduced for railroad service.

The properties of molybdenum steels are set forth in a book recently issued by the Climax Molybdenum Company, New York, from which the information in this article has been secured. The data presented are stated to be the results of tests of the ordinary commercial steels taken from the records of the users of these alloys.

The use of molybdenum as an alloy agent in steel was developed commercially under the stress of war conditions. The properties which made molybdenum alloys especially valuable for use in liberty motors, tanks and other equipment subjected to severe stresses are the high tensile strength and high elastic limit, combined with unusually large reduction of area secured by its use. Other incidental advantages are the wide range of temperature within which the tempering

well illustrated by the following results secured with a chrome molybdenum steel:

TENSILE TEST, PHYSICAL PROPERTIES, GRADE MO-2 CHROME-MOLYBDENUM STEEL.

Water quench		Elastic limit	Tensile strength	Elongation, per cent	Reduction of area, per cent
1,500 deg. F.	F.....	149,600	162,900	16.0	57.2
1,550 deg. F.	F.....	151,000	163,400	16.5	57.3
1,600 deg. F.	F.....	148,800	163,600	17.0	57.3
1,650 deg. F.	F.....	148,500	161,400	16.5	58.9
1,700 deg. F.	F.....	149,500	162,400	16.5	56.8

Tests made on 1¼-in. round bars, all drawn at 1,000 deg. F. Analysis: carbon .23 to .30, manganese .50 to .80, chromium .80 to 1.10, silicon .10 to .20, molybdenum .25 to .40.

This is further illustrated by the photomicrographs in Fig. 1. The uniformity of hardening throughout large sec-

Fig. 2. Comparative Brinell Hardness of Chrome Molybdenum Steel (shown on the left) and a Similar Alloy Steel

tions is shown by Fig. 2, in which the Brinell readings on 3½-in. square sections of chrome-molybdenum and another similar alloy steel are compared.

Molybdenum has been used for many years in the manu-

Fig. 1. Microphotographs of Chrome Molybdenum Steel Showing Similarity of Microstructure at Various Drawing Temperatures. Specimens quenched in oil from 1,600 Deg. F. and drawn as shown. Magnification 400 diameters.

and drawing operations can be performed without greatly altering the physical properties of the steel, the uniformity of hardening throughout large sections, the reduction of warpage during manufacture and the unusual toughening of the steel.

The relatively small variation in the physical properties which results from a change in the quenching temperature is

facture of high-speed steel with six per cent of molybdenum and came into disuse with the tool steel trade because the composition was unfavorable to uniform results after redressing the tool. This defect was accounted for by volatilization, but at the present time molybdenum tool steels are being produced in Great Britain and here in commercial tonnages, with cobalt as a satisfactory stabilizer. All of the steels described

in this article contain molybdenum in amounts ranging from .3 to .8 per cent. In these steels there is no volatilization in production or in use. Heretofore, the properties imparted by fractional percentages of the element were relatively little understood and the alloys of molybdenum formerly used were often impure and the results secured were therefore not uniform. Furthermore, molybdenum was classed as a rare element, not available in commercial quantities.

During the war large deposits of molybdenum were developed at Climax, Colo. From this ore ferro-molybdenum and calcium molybdate were produced in quantities, and a large tonnage of various types of molybdenum steel was manufactured. The molybdenum is introduced into the steel either in the bath or in the ladle, preferably in the bath, and can be used in steels produced by the open hearth, electric or crucible process.

The alloys which have been developed thus far are of four general types, chrome-molybdenum, chrome-nickel-molybdenum, nickel-molybdenum and chrome-vanadium-molybdenum steels. Each of these alloys is made in a number of grades

Fig. 3. Properties of Chrome Molybdenum Steel Quenched in Water and Drawn at Various Temperatures

All tests made with 1 1/4-in. square bars quenched from 1,600 deg. F. Hardening range 1,500 to 1,700 deg. F. Bars heat treated in full size, then machined to .505 in. diameter. Approximate average analysis: carbon .32 per cent, manganese .55 per cent, silicon .15 per cent, chromium .90 per cent, molybdenum .37 per cent.

with varying percentages of the metallic elements and varying carbon content. The chemical compositions are as follows:

CHROME-MOLYBDENUM STEELS

TYPE MO

	Per cent
Carbon	.15 to .40
Manganese	.40 to .80
Chromium	.70 to 1.10
Molybdenum	.25 to .40

TYPE MS

Carbon	.40 to .50
Manganese	.60 to .90
Silicon	.10 to .20
Chromium	.80 to 1.10
Molybdenum	.25 to .40

CHROME-NICKEL-MOLYBDENUM STEEL

TYPE LM

Carbon	.25 to .35
Manganese	.50 to .80
Silicon	.10 to .25
Chromium	.70 to 1.00
Nickel	2.75 to 3.25
Molybdenum	.30 to .50

NICKEL-MOLYBDENUM STEEL

TYPE NM

Carbon	.20 to .40
Manganese	.30 to .50
Nickel	3.00 to 5.00
Silicon	.10 to .20
Molybdenum	.30 to .70

CHROME-VANADIUM-MOLYBDENUM STEEL
TYPE VM

Carbon	.30 to .40
Manganese	.40 to .60
Chromium	.70 to 1.00
Vanadium	Trace to .17
Molybdenum	.35 to .85

Fig. 4. Properties of Chrome Molybdenum Steels Quenched in Oil and Drawn at Various Temperatures

Method of testing and average analysis same as given in Fig. 3, except quenching temperature, which was 1,700 deg. F.

Properties of Chrome-Molybdenum Steel

The steels of the chrome-molybdenum series are made in four grades of varying carbon content, the analyses being as follows:

TYPE MO

(Molybdenum .25 to .40 per cent)

	Grade MO-1	Grade MO-2	Grade MO-3
Carbon	.15 to .23	.23 to .30	.30 to .40
Manganese	.40 to .70	.50 to .80	.50 to .80
Chromium	.70 to 1.00	.80 to 1.10	.80 to 1.10
Silicon	.10 to .20	.10 to .20	.10 to .20
Sulphur and phosphorus each	.04 maximum.		

Fig. 5. Effect of Higher Molybdenum Content on Chrome Molybdenum Steel, Water Quenched

Approximate average analysis: carbon .36 per cent, manganese .52 per cent, silicon .13 per cent, chromium 1.00 per cent, molybdenum .76 per cent. Method of testing same as given in Fig. 3. Hardening range 1,500 to 1,700 deg. F.

This type is suitable for general machinery parts subjected to high stresses. With low carbon content it makes an extremely tough case-hardening steel, while the grades having higher carbon percentage are used principally for oil-quenched gears and large forgings. The grade MO-3 is rec-

ommended for driving axles, main and side rods, piston rods and crank pins. The properties developed by water and oil-quenching are shown by the diagrams reproduced in Figs. 3 and 4. The reduction of area, which is an index of the toughness and satisfactory machining qualities of the steel is unusually high. It will also be noted that the tensile strength

Fig. 6. Effect of Higher Molybdenum Content on Chrome Steel, Oil Quenched

Approximate average analysis same as given in Fig. 5. Method of testing same as Fig. 4.

and elastic limit decrease slowly as the drawing temperature is increased. This is a distinct advantage, as the high drawing temperature gives greater resistance to dynamic stresses or fatigue and the slow falling off of the physical properties gives a greater permissible range in heat treatment.

The effect of an increase in the molybdenum content is shown by a comparison of the test in Figs. 3 and 4 with

Fig. 7. Properties of Nickel Molybdenum Steel, Drawn at Various Temperatures

All tests made with 1 1/8-in. round bars quenched in oil from 1,500 deg. F. Hardening range 1,450 to 1,650 deg. F. Heat treated in full size and then machined to .505 in. diameter. Approximate average analysis: carbon .33 per cent, manganese .25 per cent, silicon .18 per cent, nickel 4.50 per cent, molybdenum .58 per cent.

Figs. 5 and 6, the curves of the latter charts representing tests of steel containing .76 per cent molybdenum, whereas Figs. 3 and 4 were plotted for steel with .37 per cent molybdenum.

Molybdenum Spring Steels

The type MS has a higher carbon content than the type MO and is designed especially for springs, rivet sets and forging dies. The analysis range is as follows:

Carbon	.35 to .60 per cent
Manganese	.60 to .90 per cent
Silicon	.10 to .20 per cent
Chromium	.80 to 1.10 per cent
Molybdenum	.25 to .40 per cent

The physical properties of this steel are:

Elastic limit	180,000 to 210,000 lb. per sq. in.
Tensile strength	200,000 to 230,000 lb. per sq. in.
Elongation, per cent.	12 to 15
Reduction of area, per cent.	37 to 45

The chrome-nickel-molybdenum and chrome-vanadium-molybdenum steels are not considered commercially applicable for railroad service. However, the nickel-molybdenum steels are applicable for practically the same service as the type MO-3.

Nickel-Molybdenum Steels

The addition of molybdenum to nickel steel increases the elastic limit and the toughness and ductility for given elastic limits. It also permits of heat treating the steels within a wider temperature range without a detrimental effect on the physical properties.

The grade recommended for axles and similar parts is the NM-2, which has the following chemical composition:

Carbon	.30 to .40 per cent
Manganese	.25 to .45 per cent
Nickel	3.00 to 5.00 per cent
Silicon	.10 to .20 per cent
Molybdenum	.30 to .70 per cent

The table below shows the slight variation in the properties caused by marked differences in the quenching temperatures.

TABLE I.—PHYSICAL PROPERTIES

Oil quench	Elastic limit	Tensile strength	Elongation, per cent	Red. of area, per cent
1,450 deg. F.	164,600	173,800	16.0	53.4
1,500 deg. F.	166,500	176,000	15.5	55.3
1,550 deg. F.	165,100	175,000	15.5	54.0
1,600 deg. F.	164,900	173,300	15.5	55.6
1,650 deg. F.	166,000	174,400	15.0	55.0

Analysis: Carbon .33 per cent, manganese .25 per cent, silicon .18 per cent, nickel 4.50 per cent, molybdenum .58 per cent.

The effect of a variation in the drawing temperature is illustrated in Fig. 7.

The data presented in the foregoing charts and tables have been taken from tests of material used in automobiles, aviation engines and tanks, the sections in all cases being relatively small. The difference in the service conditions encountered in railroad equipment and the larger sections used, make it difficult to predict the behavior of molybdenum steels in locomotive parts. From the results already secured the types described above appear to have properties that would make them well adapted for use under severe service conditions and the results of the introduction of this type of alloy steel will therefore be of great interest.

A CENTRIFUGAL SYSTEM OF CASTING PIPES.—The National Iron Corporation, of Toronto, is casting iron pipes by a centrifugal system, devised by a French engineer, which it is claimed will revolutionize the pipe-making industry by reason of the fact that it produces a stronger pipe and one that will not burst under a high pressure. The iron, at very high temperature, is poured into a trough, which is immediately introduced into a revolving water-cooled mould and turned over. Centrifugal force distributes the metal evenly, and as graduated ladles are used there is no waste. The finished pipe is withdrawn a few seconds after the iron is poured. Tests indicate greater strength and closer texture than result from the ordinary casting in sand.—*The Engineer, London.*

INERTIA FORCES OF THE REVOLVING AND RECIPROCATING PARTS IN AN ATLANTIC TYPE LOCOMOTIVE

BY EDWARD L. COSTER
Assoc. Am. Soc. M. E.

In the following calculations is presented in detail a determination of the horizontal and vertical disturbing forces exerted on the main crank pins at the dead points and quarters, respectively, by the inertia of the reciprocating parts, the main rods and the side rods of a recently built heavy Atlantic type superheated steam locomotive, having 23½-in. x 26-in. cylinders, 80-in. drivers, and 205-lb. boiler pressure, and in which, as the result of very careful design and the use of heat-treated steel, the weights of these parts have probably been reduced approximately to the minimum consistent with the requisite strength.

Denoting the front and back dead points by *F* and *B*, respectively,

- Let *s* = piston strike in inches
- D* = driving wheel diameter in inches
- R* = crank radius in feet
- L* = length of the main rod, center to center, in feet
- X* = distance of the center of gravity of the main rod from the crank pin center in feet
- k* = radius of gyration of the main rod about the axis of the crosshead pin in feet
- W* = weight of the reciprocating parts in pounds
- W'* = weight of the main rod in pounds
- W''* = weight of the main rod at the center of the crank pin in pounds
- W'''* = weight of the side rod at the center of main crank pin in pounds
- W_m* = counterweight at crank radius in the main driver for the reciprocating parts, main rod and the main pin end of the side rod in pounds
- W_r* = counterweight at crank radius in the front driver for the reciprocating parts in pounds
- P_r* = inertia of reciprocating parts at *F* in pounds
- P_b* = inertia of reciprocating parts at *B* in pounds
- P_r'* = horizontal inertia of main rod at *F* in pounds
- P_b'* = horizontal inertia of main rod at *B* in pounds
- C'''* = centrifugal force of *W'''* in pounds
- C_m* = centrifugal force of *W_m* in pounds
- C_t* = centrifugal force of (*W_m* + *W_r*) in pounds.

For the locomotive under consideration, the dimensions and weights are as follows:

<i>s</i> = 26 in.	<i>W</i> = 730.5 lb.
<i>D</i> = 80 in.	<i>W'</i> = 720.0 lb.
<i>R</i> = 1.083 ft.	<i>W''</i> = 440.5 lb.
<i>L</i> = 11.323 ft.	<i>W'''</i> = 231.0 lb.
<i>X</i> = 4.395 ft.	<i>W_m</i> = 977.5 lb.
<i>k</i> ² = 64.974 ft. (approximately).*	<i>W_r</i> = 306.0 lb.

Then substituting feet for inches for the quantities within the braces of formulae (2a), (3a), (6a) and (7a), given in the writer's article entitled the Longitudinal Disturbing Forces in Locomotives,† published in the *Railway Mechanical Engineer* for July, 1919, at diameter speed we have:

$$P_r = 1.6 \times 730.5 \times 26 \left\{ 1 + \frac{1.083}{11.323} \right\} = 30,388.8 \times 1.096 = 33,306 \text{ lb.}$$

$$P_b = 1.6 \times 730.5 \times 26 \left\{ 1 - \frac{1.083}{11.323} \right\} = 30,388.8 \times 0.904 = 27,471 \text{ lb.}$$

$$P_r' = 1.6 \times 720 \times 26 \left\{ 1 + 1.083 \frac{2 \times 4.395 - 11.323}{11.323^2} \right\} = 29,952 \times \frac{0.979}{29,323} = 29,323 \text{ lb.}$$

$$P_b' = 1.6 \times 720 \times 26 \left\{ 1 - 1.083 \frac{2 \times 4.395 - 11.323}{11.323^2} \right\} = 29,952 \times \frac{1.021}{30,581} = 30,581 \text{ lb.}$$

From formula (1a) in the article above referred to, at diameter speed:

$$C''' = 1.6W'''s = 1.6 \times 231 \times 26 = 9,610 \text{ lb.}$$

$$\text{and } C_t = 1.6(W_m + W_r)s = 1.6(977.5 + 306) \times 26 = 53,394 \text{ lb.}$$

*The period of oscillation of this main rod about the axis of the crosshead pin has not as yet been determined. The value of *k*² here given is that of a rod of equal length and almost identical position of mass center, for which *k*² was calculated by the writer from the results of an oscillation test.

†These formulae were stated as follows, except that for convenience the weight designations have been changed in this article:

$$(2a) : P_r = 1.6W_s \left\{ 1 + \frac{R}{L} \right\}; \quad (3a) : P_b = 1.6W_s \left\{ 1 - \frac{R}{L} \right\};$$

$$(6a) : P_r' = 1.6W's \left\{ 1 + R \frac{2X - L}{L^2} \right\}; \quad (7a) : P_b' = 1.6W's \left\{ 1 - R \frac{2X - L}{L^2} \right\}$$

Therefore at 80 miles an hour the total horizontal inertia forces on the main crank pin are:

$$P_r + P_r' + C''' = 33,306 + 29,323 + 9,610 = 72,239 \text{ lb. at } F$$

$$P_b + P_b' + C''' = 27,471 + 30,581 + 9,610 = 67,662 \text{ lb. at } B$$

$$\text{Difference} = 4,577 \text{ lb.}$$

Consequently the unbalanced longitudinal inertia forces are:

$$P_r + P_r' + C''' - C_t = 72,239 - 53,394 = 18,845 \text{ lb. at } F$$

$$P_b + P_b' + C''' - C_t = 67,662 - 53,394 = 14,268 \text{ lb. at } B$$

$$\text{Difference} = 4,577 \text{ lb.}$$

Turning now to the quarters, as demonstrated in Henderson's "Locomotive Operation," 2d edition, pages 51-57 and page 516 (this discussion is too long for inclusion here), at diameter speed the resultant vertical upward and downward force in pounds exerted on the main crank pin at the top and bottom quarters, respectively, by the inertia of the reciprocating parts and the inertia and weight of the main and side rods is

$$R = 1.6s \left\{ W' \left[\frac{k^2}{L^2} + \frac{X}{L} \frac{R^2}{L^2 - R^2} \right] + W \frac{R^2}{L^2 - R^2} \right\} + C''' \mp (W'' + W''')$$

the negative and positive signs preceding the last term corresponding to the top and bottom quarters, respectively.

Substituting the above given values, then at 80 miles an hour:

$$R_t = 1.6 \times 26 \left\{ 720 \left[\frac{64.974}{11.323^2} + \frac{4.395}{11.323} \times \frac{1.083^2}{11.323^2 - 1.083^2} \right] + 730.5 \frac{1.083^2}{11.323^2 - 1.083^2} \right\}$$

+ 9,610 - (440.5 + 231) = 15,549 + 9,610 - 671.5 = 24,487.5 lb. at the top quarter.

and $R_b = 15,549 + 9,610 + 671.5 = 25,830.5 \text{ lb. at the bottom quarter.}$

The difference of 1,343 lb. between the top and bottom quarters results from the weights of the main and side rods at the main crank pin.

Since at this speed

$$C_m = 1.6W_ms = 1.6 \times 977.5 \times 26 = 40,664 \text{ lb.,}$$

at the top quarter the net increase in the static wheel pressure (34,000 lb.) of each main driver, or the "dynamic augment," is

$$C_m - R_t = 40,664 - 24,487.5 = 16,177 \text{ lb.,}$$

and at the bottom quarter the net decrease in the static wheel load is

$$C_m - R_b = 40,664 - 25,830 = 14,834 \text{ lb.}$$

This is a total variation of 31,011 lb. per semi-revolution.

While the maximum speed of this locomotive is supposed to be 70 miles an hour, it has been operated at considerably higher velocities, hence the assumption of 80 miles an hour as a basis for the calculation of the maximum inertia forces is not excessive.

The foregoing figures indicate that, even with the most refined design and the use of the best materials now obtainable, the maximum disturbing forces at the dead points and quarters due to the inertia of the reciprocating parts, main and side rods are of great intensity, and they emphasize the vital importance of the most careful design and construction of these parts in order that their weight may be reduced to the practical minimum. For many years this fact has been universally recognized in Europe, but in this country, with a few notable exceptions, of which the locomotive here considered is one of the best examples, it has not received the attention which it unquestionably deserves.

CRANE HOOKS, depending from large traveling cranes in machine shops, ought to be painted white, so as to be easily seen. With this improvement in visibility workmen will be less likely to run against a hook or to be struck by one which is moving. This point is brought out in "National Safety News" No. 318.

GAR DEPARTMENT

A SELF-CLEARING HOPPER CAR BUILT EXCLUSIVELY FOR GRAIN SERVICE

In the construction of freight cars there is apparently a tendency to adapt them to carrying a wide variety of lading. It is therefore interesting to note that the Canadian Pacific has recently built a large capacity hopper car which is designed to handle but one commodity, grain. This car was constructed to determine by actual service test the net advantages to be obtained from a grain-tight self-clearing car of maximum tonnage capacity, as compared to standard box cars of ordinary capacity.

The limiting tonnage adopted as the basis of the design

The car is all-steel, with the exception of the running board and the ridge on top of the center sill. The general design is practically the same as is commonly used for coal cars of equal capacity, except that this car is built with a steel roof. The roof is provided with three hatch openings on each side of the running board, which are located respectively at the center of the car and directly above the two-end hoppers.

The hoppers are arranged four on each side of the center sill. The hopper openings are purposely made relatively small and the frame and slides are machined and carefully fitted. The slides are opened and closed by a rack and pinion arrangement and are locked by means of a sealing pin

Canadian Pacific 75-Ton Hopper Grain Car

is the maximum capacity of four M. C. B. axles having 6-in. by 11-in. journals. The length was determined by the distance from center to center of unloading hoppers in the modern elevators at Montreal and West St. John, there being one elevator having hopper centers spaced 48 ft. The height was determined by the actual cubic space required to contain the full load of wheat, plus an allowance of at least 12 in. on top to permit of full load being placed in the car without trimming. To meet this condition it was necessary to make the height at the eaves 13 ft. The width at the eaves is 10 ft. 3 in.

passing through the slide and hopper frame. The trucks are of the Vulcan type built to U. S. R. A. dimensions. The light weight is 59,700 lb., making the allowable load limit 150,000 lb.

The car having given satisfactory performance on its initial trip between Port McNicoll, Ontario and Montreal, it has been placed in regular service between the same port and West St. John. If this type of car proves suitable for grain service it will effect a large saving by eliminating leakage and doing away with the use of grain doors and cooperating material.

THE EFFICIENCY OF HAND BRAKES

BY GEO. L. FOWLER

Circular No. S III-11, issued by the American Railroad Association, Section III—Mechanical, in May, 1919, reads in part as follows:

“An eight inch brake cylinder has a value of practically 2,500 lb. at 50 lb. pressure and the value of a 10-in. cylinder at 50 lb. pressure is for all practical purposes 3,950 lb., and all parties concerned should use these cylinder values as a basis in proportioning the levers in the air brake system for the percentage of braking power recommended for the air brake.

“With the body and truck levers properly proportioned for 60 per cent braking power, as specified in the foregoing, and based on the formulae and diagrams shown herein, the hand brake wheel or hand brake ratchet lever, brake staff at chain, and the hand brake leverage between brake staff and cylinder shall be so proportioned that a force of 125 lb.

FIG. 1.

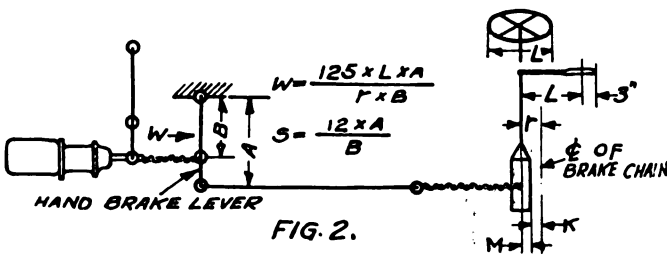

FIG. 2.

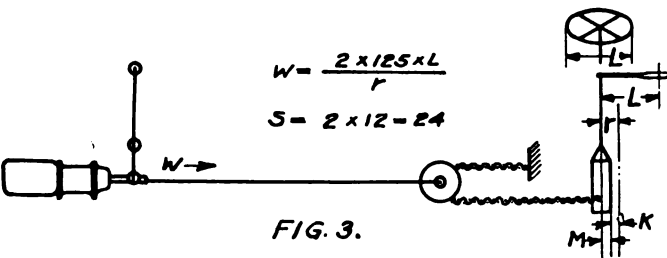

FIG. 3.

W = equivalent pull in lb. at brake cylinder piston rod.
 125 = assumed lb. pull on rim of brake wheel, or on hand brake lever in from outer end.
 L, Y, A, & B = Dimensions in inches.
 r = M + K.
 M = radius, in inches, of brake staff drum.
 K = distance, in inches, from face of brake staff drum to center line of brake chain. for 3/8 in. brake chain K = 1/2 in.
 S = minimum chain slack, in inches, to be taken up on brake staff.
 12 = piston travel in inches.
 Note:—Dimension B not to be less than 11 in.

Formulae for Calculating Hand-Brake Power Given in Circular SIII-11

at the rim of the brake wheel or three inches from outer end of hand brake ratchet lever will develop an equivalent load *W* at the brake cylinder piston of not less than 2,500 lb. and 3,950 lb. respectively for cars having eight inch and 10-in. cylinders. This will insure a minimum hand brake power at the shoes of 60 per cent of the empty car weight.

“A single sheave wheel applied to end of hand brake rod should be treated as two-to-one lever in figuring the hand brake power.”

These statements are apt to create a wrong impression if allowed to stand at their face value without question. The purpose of the circular is to give a method of calculating the

actual brake shoe pressures to be obtained and in its presentation two assumptions are made with which the writer cannot agree. Upon these assumptions depends the whole value of the calculations for the determination of brake shoe pressures.

The first is that a pull of 125 lb. on the brake wheel should be used as the power available for the application of the brakes. That this can be done there is no doubt, but the writer has found in his investigations that a man weighing from 150 lb. to 160 lb. cannot be depended on to pull more than 75 lb. or 80 lb. on the brake wheel. A fair rough estimate of what a man can pull is one-half his weight, so that to pull 125 lb. would mean either the use of a club or that the work would be done by a man of more than ordinary strength or weight.

Then it assumes that the efficiency of the brake rigging is 100 per cent. A few years ago the writer had occasion to make a series of brake tests in which it was desired to maintain a constant pull on the brake chain of 450 lb. A dynamometer with an electrical contact was placed in the chain and so arranged that a bell would be rung and kept ringing so long as a pull of 450 lb. was maintained. An increase or decrease of pull broke the circuit and the bell stopped ringing. It was noticed that the apparent exertion which the motorman put on his work varied greatly though the chain pull remained constant. A dynamometer was then put on the brake handle and it was found that the pull required to exert a stress of 450 lb. on the chain varied from 35 lb. to 56 lb. and once after it had required 55 lb. to produce the 450-lb. chain pull, the pull on the brake handle was relaxed to 40 lb. without any decrease in the pull on the chain.

Later, in tests with a high grade geared hand brake its efficiency was found to range from 70 to 80 per cent and that of the plain staff brake to be rarely over 60 and often as low as 50 per cent. From this it is evident, that it will be quite out of the question to realize the full value obtained by the calculations in the circular. The only value of the calculations is that by the use of the original 125-lb. pull a theoretical result can be obtained which may be discounted down to that actually reached.

Then the circular states that “a single sheave wheel applied to the end of hand brake rod should be treated as a two-to-one lever in figuring hand brake power.”

A number of tests have shown this to be quite wrong. The frictional resistance of an ordinary cable chain running over a sheave in the usual condition accounts for fully 25 per cent of its theoretical efficiency.

On the basis of these figures and observations, the original 125-lb. pull on the brake wheel should be reduced to 75 lb. The efficiency of the brake staff should be reduced from 100 to 60 per cent and that of the sheave to 75 per cent. Taken as a whole, the combination loses 40 per cent in basic pull, 30 to 40 per cent in the brake staff and 25 per cent for the sheave, with the result that the ultimate stress applied to the cylinder lever is only about 27 per cent of that calculated on the assumption of a 125-lb. pull. If no reduction is allowed for at the brake wheel, the actual stress applied to the cylinder lever will be about 70 per cent of that calculated with a single pull chain and about 52.5 per cent with a sheave. Of course it may be possible to make a staff that will give better results but the average as they are found will not be above these figures.

The figures given should not be set up as a final basis because of the small number of tests upon which they rest, but they are sufficient at least to prescribe caution in suggesting or accepting any theoretical basis for the calculation of the results that may be expected from hand brakes until better workmanship obtains in their construction and we know something about the efficiency of that better construction.

NEW ELECTRIC CARS BUILT FOR BRITISH LINE

**Increased Traffic Taxes Facilities; Seating and
Poor Arrangements Expedite Passenger Movement**

BY FREDERICK C. COLEMAN

THE Metropolitan Railway of London owns or is responsible for the operation of about 88 miles of railroad line in London and the vicinity. Of this 36 miles are electrically operated and the remainder is operated by steam. The steady increase in traffic on these lines has made it necessary to design the passenger equipment so that the stops at stations may be reduced to a minimum time. All of the company's rolling stock is in use, and a considerable addition to the equipment is necessary, as it is only with the greatest difficulty that opportunity is found to take trains into the shop for necessary overhauling and repairs.

To meet the needs of the service, new designs of cars have been worked out by C. Jones of Neasden, the chief electrical and locomotive engineer of the Metropolitan Railway, and trains composed of such cars have given very satisfactory service for several months past.

The new cars, as illustrated in the accompanying drawings and photographs, were built by the Metropolitan Carriage, Wagon & Finance Company, Ltd., of Saltley, Birmingham, England. Each train consists of a motor-car 51 ft. 6 in. long over end posts, with a seating capacity of 41 passengers, a third-class trailer car, 50 ft. 6 in. long, with a seating capacity of 58 passengers, and a first-class driving trailer car which usually operates as a trailer but has a drawing compartment and motor truck at one end. This car is 51 ft. 6 in. in length, with a seating capacity for 47 passengers. The total seating capacity of these three coaches is 146, and when working as a six-vehicle train, as they frequently are, the seating capacity is 292, as against 268 seats in a train

and it is confidently expected that there will be a considerable improvement in entraining and detraining facilities.

The underframes and trucks are identical with those of the

Interior of Third Class Trailer Car

existing coaches of the Metropolitan Railway. The wheels have a diameter of 3 ft. 2 in., and the truck wheel-base is

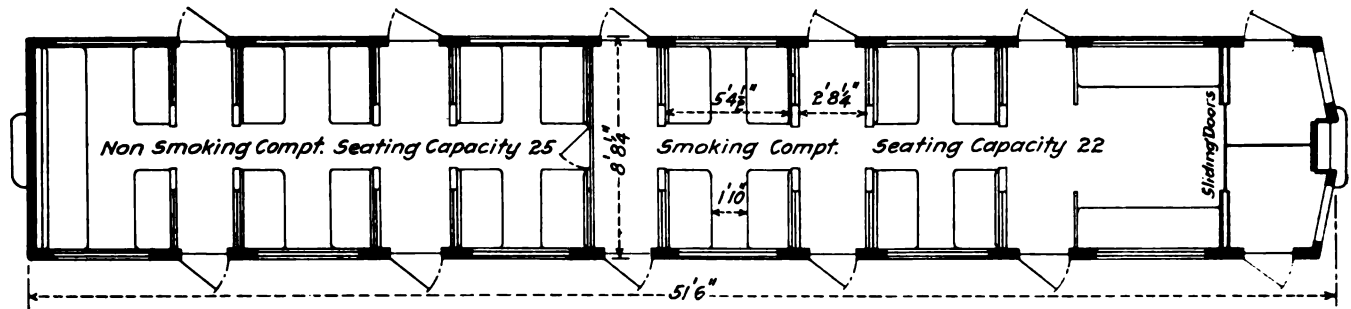

The Third Class Trailer Car

of the older types of electric rolling stock. The feature of the new vehicles is the provision of five swing doors on each side of the cars in place of the two or three sliding doors now most generally used on electric railway rolling stock,

7 ft. The new door and seating arrangements allow of improved circulation inside the cars; the inconvenience occasioned to seated passengers by others entering and leaving in the older designs is now eliminated, all gangways being

entirely unobstructed, while attention has also been paid to the improvement of lighting and heating and the provision of strap-hanging, "steadying" rails being arranged to pro-

Floor Plan of First Class Driving Trailer Car

Floor Plan of Third Class Trailer Car.

Floor Plan of Motor Car

of ventilation without draughts. A graceful dome roof has been provided, and a softening of the lights is obtained by

vide a hold for passengers, so that, while some standing will still be inevitable during the rush hours, the passengers,

First Class Driving Trailer Car

the use of frosted bulbs and opal reflectors. A new system of switches enables the guard to control the lighting and eliminate delays due to independent car light switching.

especially those of short stature, will be in a normal position. The side doors adopted are of the Metropolitan Company's standard type as fitted to compartment cars, but by means of

spring buffers and strengthening of the longitudinal framing, door controlling straps have been eliminated, as also have window straps on the third-class coaches. A new form of lock has been fitted, which, while being very easily operated, is provided with a special catch, thus providing an additional safeguard.

To add to the facilities for quick entraining and detraining on the motor-cars, arrangements have been made to allow passengers to use the luggage compartment doors. The actual luggage compartments are enclosed by Bostwick sliding lattice gates, which will also prevent the pilfering of small articles, everything being within open view.

Although the end door has been dispensed with, special handles have been provided to enable guards to pass from one car to another in cases of emergency, while stepirons have also been provided for safely alighting on the track.

Various improvements have also been made for the safety and convenience of the traveling public by the provision of an improved device for controlling the "trip" for actuating

Non-Smoking Compartment of First Class Driving Trailer Car

the brakes in emergency, and automatic window wipers to enable the driver always to maintain a clear view. The improved buffing and draw gear should give smoother starting and stopping of the train. Route number indicators of an improved type have also been embodied.

While everything has been done to promote the comfort of the passenger, that of the train crew has not been overlooked, and comfortable seats have been provided for their use.

This new type of train is materially reducing the length of time required for entraining and detraining passengers, and thus increases the carrying capacity of the entire line.

COMITY BETWEEN COMPETITORS.—Erie Railroad commuters told a story of an obliging engineer who stopped their train to give away hot water. At Heller Field, the eastern landing field of the aerial mail service on the West Orange (New Jersey) branch, Pilot P. W. Smith was ready to start with the Chicago mail when it was discovered that the water pipes at the field were frozen and there was not enough hot water on hand to start his motor. As the train came in sight, someone flagged the train, and told the engineer of the pilot's trouble. "Glad to help you out," said the engineer. Two fifty-gallon tanks were rolled up the railroad embankment and the obliging engineer filled both with hot water.—*New York Times*.

FREIGHT CAR PAINTING*

BY W. A. BUCHANAN.

The painting of freight cars has become more essential at the present time than ever before since the building of this class of railway equipment. This is especially due to the fact that steel is fast replacing wood in their construction. Therefore, greater care must be exercised in their up-keep for the life of steel is rather brief if not watched and kept painted.

When cars are new, or re-built, it is essential, especially on steel cars, to thoroughly clean and paint all laps. Red lead has been found to be the best material for this purpose. The preparation of steel plates is very important and if permissible, sandblasting should be done before the application of paint, for the surface thus built up has proven the most satisfactory method for preventing corrosion, and paint adheres to the surface much better.

Freight car bodies of wood construction should be painted underneath all corner irons, or plates, before these parts are applied to cars. The roof boards should at least receive one good coat of paint before the running boards are applied. As soon as possible after the carpenters finish their work, the car should be primed. A mixture of some good metallic paint ground in oil, thinned to working consistency, has been found excellent material for this purpose. New work should receive at least three coats of paint if possible.

When roofs are of steel construction, special care should be exercised in painting them with some good steel car paint. When galvanized iron is used, the surface should be primed with galvanized iron primer for ordinary steel primers will not adhere to galvanized iron very long after being painted. This is very essential and should be carefully checked.

The standardization of freight car stencilling is one of the greatest problems confronting the master painter today, and for that reason the Master Painters' Association for years has been trying to show the necessity for adopting some general standard of letter and numeral for this class of equipment. No one item enters more into the expense of painting freight cars than does the making and upkeep of stencils. It necessitates the employment of a high rated employee in the first place to make the stencils and keep them in repair, and when we stop to consider the fact that most repair yards are obliged to give nearly as much attention to the repairs of foreign equipment as to system cars, some adequate idea may be had of the amount of time and material necessary to maintain stencils which of necessity must be kept in stock in order to replace standards of the various railroads. I might say in passing that no two roads have the same standard, either in style or shape of letters or numeral, although they are of Roman or Grecian style. This it will readily be observed necessitates an enormous outlay that could be eliminated if a standard could be agreed upon.

Next in order, I would recommend a standard grouping of the stencilling as follows: The initials or name of the road, together with the numbers of the car, should be placed to the left of the door. The lower markings should include the capacity of the car, cubical measurements, class, date built, weight, safety appliance markings, or any other marking of the above character. We then have grouped all of the information car inspectors or car checkers require to handle their work with dispatch. To the right of the door can be placed information showing the class of commodities the car was designed to carry. The lower marking should also show the length, height and width of the car. On the end of the car the initials of the road and the number of the car should be shown, placed at the right-hand corner of the car.

*From a paper presented before the Niagara Frontier Carmen's Association.

The lower markings should show the kind of triple valves, coupler shanks, draft rigging and brake beams with which the car is equipped.

Next in importance is the adequate paint protection required to keep air brake equipment in proper shape in order to insure against rust deterioration. Proper stencilling should be maintained at all times showing the dates when triples and cylinders were last cleaned.

A uniform standard of stencilling trucks is very important and should show the initials of the road and the number of the car to which the trucks belong. This information is very essential when cleaning up wrecks in order to enable men to sort out the right trucks, as the car body in many cases is completely destroyed, thus making it impossible to identify the car unless truck markings are available.

Proper facilities for handling the work is a most essential feature. This should include special trackage equipped with

USE OF THE ORIGINAL RECORD OF REPAIRS

In order to provide a uniform blank for reporting repairs made to foreign cars which would embody the necessary information for the preparation of billing repair cards and serve as a permanent record for the files of the company making repairs, a form, designated as the "Original Record of Repairs," which is shown on page 158 of the 1919 code of rules has been adopted. The importance of a uniform record of this kind has been generally recognized for some time, and if properly used it will simplify repair card writing to a great extent. Heretofore clerks writing up repair cards have been obliged to supply a great deal of information especially under the heading "Why Made," which has resulted in numerous cases of disputed car repair bills and unnecessary correspondence which could have been avoided had car

Reverse Side of the Form Used for Light Repairs

air lines and a maximum pressure of from 80 to 90 lbs. in order to air dust and spray the lower portions of cars and trucks. These tracks could be covered which would insure the conditions necessary to protect the men and the work after being painted and would also permit the painting operation during the winter months when traffic is lightest and freight car equipment can be spared to the best advantage.

been properly checked at the time repairs were made. Erroneous prices, weights, etc., have also caused additional correspondence which would have been eliminated had a proper description of the material applied been given.

The most important feature, however, in the use of this form is the inspection of car before repairing is begun, which should not only provide an accurate record of the actual condition of all parts renewed, but should also result in great saving of ma-

material as none but defective parts reported would be removed. The forms must be complete and accurate and must be signed by the person inspecting the car before repairs are begun and also by the person completing the report to vouch for the correctness of the items. Any corrections must be made by the person or persons signing the record. Billing repair cards must agree with the Original Record of Repairs in regards to details as far as is practicable.

The forms shown below are samples of the Original Record of Repairs used by one railroad for heavy and light repairs. The form for heavy repairs is 8½ in. by 14 in. and the reverse side provides space for recording as many as four

mile of track would be 13 of about 14 short tons capacity each.

There were in old Russia, in 1917, 11 car factories, as follows: In Reval, 1; Petrograd, 2; Tver, 1; Moscow, 1; Rybinsk, 1; Kolomna, 1; Bormovo, 1; Briansk, 1; Nicolaev, 1, and Ust-Katavsk, 1. Kerensky placed among these works orders for 200,000 cars of 20 tons each, shipment to begin in 1920 and extend over five years. The position of the Reval shops would afford an early start in car building not enjoyed by any other shops. The works are running at about 25 per cent capacity repairing locomotives and cars for the Esthonian Government. The plant is intersected

Portion of a Typical Repair Record

pairs of wheels, while the form used for light repairs and cars on the loaded repair tracks is 8½ in. by 7 in. and provides a space for recording renewal of two pairs of wheels only. Each form provides space for Joint Evidence, Defect Card record, also seal records and record of material ordered from owners. Under the heading "Remarks" any information as regards the condition of the lading, etc., which might prove beneficial is also reported. Such records prove valuable assets if correct and complete but an incomplete record is worthless and time consumed in preparing it represents a total loss.

CAR BUILDING IN RUSSIA

Commerce Reports in a recent issue publishes an interesting letter from John P. Hurley, consul at Riga, relative to ship and car building facilities at Reval. The letter is dated January 26. Those portions of it relating to car building are given in part as follows:

The position of the Dwigatel car shops is especially favorable for supplying cars to the railroads of Russia. None of the machinery of this plant was evacuated on the approach of the Germans, owing to protests of the workmen; hence the plant is complete. Judging by the condition of rolling stock in Latvia and Esthonia, the condition of rolling stock throughout Russian must be very poor. Prior to the war there were about 600,000 freight cars in Russia, whose railway system covered about 45,000 miles. The car census per

throughout with railways and similarly connected with the town. Erecting shops in good condition would permit work on about 200 cars simultaneously. A supply of wheels and axles, sufficient for immediate needs, is on hand, but the factory is in urgent need of tires and spring steel. The power plant is complete and of about 1,500 horsepower. The machine shop is a two-story building of limestone (as are all other buildings) about 90 feet by 250 feet, and completely equipped with requisite machinery. The forge shops are about 300 feet square and equipped with about five 3-ton drop hammers. As with every factory in this country, the greatest need is coal, coke and lubricating oil.

Wages in Reval run from 30 to 60 Esthonian marks a day, but owing to the recent disturbance will undoubtedly increase. Here, as in every other country, labor has demanded increased wages and shorter working hours. At present 18 to 30 marks a day is paid for unskilled labor, and 40 to 60 marks a day for skilled labor. The rate of exchange is 100 marks to the dollar for currency, and 90 to the dollar for checks. The base value of the mark is 25 to the dollar.

The director of the car-building plant states that practically all of his skilled workmen still remain, and that the shops have worked continuously. Both the shipbuilding yards and the Dwigatel car building works deserve attention, and it is extremely probable that capital of other countries is interested. The belief obtains here that in the United States alone can requisite capital be obtained, and American prestige among business interests is very high.

THE INSPECTION OF FREIGHT EQUIPMENT*

Safety Appliance Standards and Federal Inspection; Doors, Roofs and Air Brakes

BY L. K. SILLCOX

Master Car Builder, Chicago, Milwaukee and St. Paul

One hand hold over each ladder is to be provided. They must be $\frac{5}{8}$ in. in diameter of wrought iron or steel. The tread must be not less than 16 in. with a minimum clearance of 2 in. They shall be securely fastened by not less than $\frac{1}{2}$ -in. bolts with the nut outside (if possible) riveted over, or with $\frac{1}{2}$ -in. rivets, located one parallel to the tread of each ladder not less than 8 in. nor more than 15 in. from the edge of the roof.

There are exceptions on refrigerator cars when ice hatches prevent; on such cars the location may be nearer the edge of roof. Other exceptions are on caboose cars; where stiles of ladders extend 12 in. or more above the roof, no other roof hand holds are required.

Another type of roof hand hold used is one right angle hand hold which may take the place of two adjacent specified roof hand holds, provided the dimensions and locations coincide (M. C. B. rules require them to be without weld). The special requirements for these right angle hand holds provide that they must have an extra leg, securely fastened to the car at the point of the angle. This is a necessary safety precaution.

Cupola Handholds

Cupola hand holds to be provided are one or more, located as follows: one continuous hand hold extending around the top of the cupola, not more than 3 in. from the edge of the cupola roof, or four right angle hand holds, one at each corner not less than 16 in. in clear length from the point of the angle, which may take the place of the one continuous hand hold specified, if the locations coincide.

Running Boards

Running boards must be made of wood, running the full length of the car in the center of the roof, and securely fastened, the exception being that on caboose cars with cupola, longitudinal running boards shall extend from the cupola to the ends of the roof. Other conditions specified are that the length and width of running boards may be made up of a number of pieces securely fastened to saddle blocks, with bolts or screws, but the running boards must not be cut or hinged at any one point.

Additional requirements for cars with outside metal roofs provide that two latitudinal extensions shall be used from the longitudinal running boards to the ladder location. The proper width of these boards is as follows: the longitudinal running boards shall be not less than 18 in. in width, and the latitudinal extensions not less than 24 in. in width. The following cars are excepted: tank cars without side sills, tank cars with short side sills and end platforms and tank cars without end sills. The proper width of running boards on the above named cars is: minimum width 10 in. on the side and 6 in. on end.

Cars not requiring latitudinal extension are: refrigerator cars, on account of ice hatches.

Longitudinal running board and clearances are specified as follows: the ends shall be not less than 6 in. nor more than 10 in. from a vertical plane parallel with the end of the car, exceptions being: tank cars without side sills, tank cars with

short side sills and end platforms and tank cars without end sills. The end clearance specified for these cars is not less than 6 in., the measurement to be taken from a line passing through the inside face of the knuckle, when closed with the coupler horn against the buffer block, the end sill or the back stop.

If running boards extend more than 4 in. from the edge of the roof, they must be supported for the full width by substantial metal braces.

The following classes of tank cars must be equipped with running boards: tank cars without side sills, tank cars with short side sills and end platforms and tank cars without end sills. One continuous running board is required around the sides and ends or two boards running the full length of the tank, one on each side. Tank cars having end platforms extending to the bolsters are to be equipped with running boards extending from center to center of bolsters, one on each side.

Side running boards that are applied below the center of the tank are to be put up as follows: the outside edge of such running boards shall extend not less than 7 in. beyond the bulge of the tank, these running boards to be securely fastened to the tank or tank bands.

Safety Railings

Tank cars are to be provided with one safety railing continuous around the sides and ends of the tank, or two running the full length of the tank. The proper diameter, kind of material and clearance are, on tank cars with side platforms, not less than $\frac{3}{4}$ in. iron; on tank cars without side sills and tank cars with short side sills and end platforms, tank cars without end sills, not less than $\frac{7}{8}$ in. wrought iron or steel with a clearance of $2\frac{1}{2}$ in.

The safety railings must be placed not less than 30 in. nor more than 60 in. above the running board or platform. They must be securely fastened to the tank, tank bands or posts, and secured against end shifting.

End Ladder Clearances

The end ladder clearance requirements are that no part of the car above the end sills, within 30 in. from the side of the car (except buffer block, brake shaft, brake step, brake wheel, running boards or uncoupling lever and air hose which are not to be regarded as fixtures as the word is used in the part of the order relating to end ladder clearance) shall extend to within 12 in. of a vertical plane parallel with the end of the car and passing through the inside face of the knuckle when closed, with the coupler horn against the buffer block or end sill.

Other conditions are that no other part of the end of the car or fixtures thereon above end sills, other than the exceptions named above, shall extend beyond the outer face of the buffer block.

High side gondolas and high side hopper cars are those with sides which extend more than 36 in. above the floor. Low side hopper or gondola cars are those which extend 36 in. or less above the floor.

Cars which may be equipped the same as flat cars are those with sides which extend 12 in. or less above the car floor.

*Fourth of a series of articles on this subject by Mr. Sillcox. Copyright 1920 by the Simmons-Boardman Publishing Co.

Classification of Defects To Be Reported by Federal Inspectors

The following is a list of the defects of safety appliances required to be reported by the inspectors of the Bureau of Safety.

COUPLERS AND PARTS

1. Coupler body broken.
2. Coupler body missing.
3. Coupler worn (See footnote A.).
4. Knuckle broken.
5. Knuckle missing.
6. Knuckle worn (See footnote A.).
7. Knuckle pin bent.
8. Knuckle pin broken.
9. Knuckle pin missing.
10. Knuckle pin wrong (See footnote B.).
11. Lock block bent (See footnote B.).
12. Lock block broken.
13. Lock block missing.
14. Lock block inoperative (State particulars.).
15. Lock block wrong (See footnote B.).
16. Lock block worn (See footnote A.).
17. Lock block key missing.
18. Lock block trigger missing.
19. Lock set missing.
20. Guard arm short.

Note A—Nos. 3, 6 and 16 are defects only when worn sufficiently to destroy contour line by allowing lost motion to approach the danger point as shown by A. R. A. limit gage.

Note B—Nos. 10, 11 and 15 are defects only when interfering with safe operation.

In reporting defects to couplers state names thereof.

UNCOUPLING MECHANISM.

24. Lock link bent (See footnotes A and C.).
25. Lock link broken (See footnote C.).
26. Lock link missing (See footnote C.).
27. Uncoupling lever bent (See footnote A.).
28. Uncoupling lever broken.
29. Uncoupling lever missing.
30. Uncoupling lever incorrectly applied (State particulars.).
31. Uncoupling lever wrong (See footnote B.).
32. Uncoupling chain broken.
33. Uncoupling chain missing.
34. Uncoupling chain kinked (See footnote C.).
35. Uncoupling chain too short.
36. Uncoupling chain too long.
37. End lock, or casting, bent.
38. End lock, or casting, broken.
39. End lock, or casting, loose (See footnote A.).
40. End Lock, or casting, missing.
41. End lock, or casting, incorrectly applied.
42. End lock, or casting, wrong (See footnote A.).
43. Keeper bent.
44. Keeper broken.
45. Keeper loose (See footnote A.).
46. Keeper missing.
47. Keeper incorrectly applied.
48. Keeper wrong (See footnote A.).
49. Uncoupling lever stop broken (See footnote D.).
50. Uncoupling lever stop loose (See footnote D.).
51. Uncoupling lever stop missing (See footnote D.).
52. Uncoupling lever stop incorrectly applied (See footnote D.).

Note A—Nos. 24, 27, 39, 42, 45 and 48 are defects when interfering with the proper operation of uncoupling mechanism.

Note B—No. 31, under this head include all uncoupling levers which are too long or too short. State particulars.

Note C—Give name of coupler when reporting defects Nos. 24, 25, 26 and 34.

Note D—Defects Nos. 49, 50, 51 and 52 apply to levers of the "rocking" or "pushdown" type.

State names of any patented uncoupling levers found defective.

When a clevis or clevis pin is missing so that the uncoupling chain is disconnected, report the defect as 32, which is ample detail for purpose of general inspector.

Compound defects, viz., where one defect causes another, as, uncoupling lever bent making chain too long, may be reported thus: (27-36).

VISIBLE PARTS OF AIR BRAKES.

55. Air brake cut out.
56. Cylinder and triple not cleaned within 12 months (Give date of last cleaning.).
57. Cylinder and triple last cleaned, no date.
58. Air hose missing.
59. Air hose gasket missing.
60. Air hose gasket defective.
61. Air hose coupling defective (State particulars.).
62. Angle cock missing.
63. Angle cock defective.
64. Angle cock handle broken.
65. Angle cock handle missing.
66. Train pipe broken.
67. Train pipe loose.
68. Train pipe bracket missing.
69. Cross-over pipe defective (State particulars.).

71. Cut-out cock defective (State particulars.).
72. Cut-out cock handle broken.
73. Cut-out cock handle missing.
74. Cylinder casting defective.
75. Cylinder loose.
76. Reservoir casting defective.
77. Reservoir loose.
78. Triple valve casting defective.
79. Triple valve missing.
80. Release cock defective.
81. Release cock missing.
82. Release rod broken.
83. Release rod disconnected.
84. Release rod missing.
85. Piston travel excessive (State particulars.).
86. Retaining pipe defective (State particulars.).
87. Retaining pipe missing.
88. Retaining valve defective (State particulars.).
89. Retaining valve missing.

HANDHOLDS

90. Handhold bent.
 91. Handhold broken.
 92. Handhold loose.
 93. Handhold missing.
 94. Handhold incorrectly applied (State particulars.).
 95. Handhold too short (State particulars.).
 96. Handhold not having proper clearance (State particulars.).
- In reporting defects to handholds, state in remarks location of same.
100. Coupler too high (State height.).
 101. Coupler too low (State height.).
 102. Carrier iron loose.

Inspectors must exercise judgment in determining defects of this class. See that the car is standing on an approximately level track before measurements are taken.

STEPS

105. Sill step bent.
106. Sill step broken.
107. Sill step loose.
108. Sill step missing.
109. Sill step incorrectly applied (State particulars.).
110. Sill step wrong dimensions (State particulars.).
111. Caboose platform step broken.
112. Caboose platform step missing.
114. Caboose platform step incorrectly applied (State particulars.).
115. Caboose platform, step wrong dimensions (State particulars.).
116. Side door step bent.
117. Side door step broken.
118. Side door step loose.
119. Side door step missing.
120. Side door step incorrectly applied (State particulars.).
121. Side door step wrong dimensions (State particulars.).

LADDERS

125. Ladder tread bent.
 126. Ladder tread broken.
 127. Ladder tread loose.
 128. Ladder tread missing.
 129. Ladder tread not having proper clearance (State particulars.).
 130. Ladder treads improperly spaced (State particulars.).
 131. Ladder loose.
 132. Ladder incorrectly applied (State particulars.).
 133. End ladder clearance inadequate (State particulars.).
- In reporting defects to ladders, state whether end or side.

RUNNING BOARDS

135. Running board broken.
136. Running board loose.
137. Running board missing.
138. Running board wrong dimensions (State particulars.).
139. Running board not properly secured to car (State particulars.).
140. Running board brace broken.
141. Running board brace loose.
142. Running board brace missing.
143. Running board cleat broken.
144. Running board cleat loose.
145. Running board cleat missing.
146. Latitudinal extension broken.
147. Latitudinal extension loose.
148. Latitudinal extension missing.
149. Latitudinal extension wrong dimensions (State particulars.).
150. Latitudinal extension not properly secured to car (State particulars.).

HAND BRAKES

151. Brake shaft bent.
152. Brake shaft broken.
153. Brake shaft loose.
154. Brake shaft incorrectly applied (State particulars.).
156. Brake shaft top nut missing.
157. Brake shaft cotter key or ring at bottom of shaft missing.
158. Brake shaft wrong dimensions (State particulars.).
159. Brake shaft with weld.
160. Brake wheel broken.
161. Brake wheel loose.
162. Brake wheel missing.
163. Brake wheel incorrectly applied (State particulars.).
164. Brake wheel wrong dimensions (State particulars.).
165. Ratchet wheel broken.
166. Ratchet wheel loose.
167. Ratchet wheel missing.
168. Ratchet wheel incorrectly applied (State particulars.).

169. Ratchet wheel wrong dimensions (State particulars.).
170. Ratchet wheel, insufficient teeth (State particulars.).
171. Brake pawl broken.
172. Brake pawl loose.
173. Brake pawl missing.
174. Brake pawl incorrectly applied (State particulars.).
175. Brake step broken.

256. Cylinder rod disconnected.
257. Cylinder rod missing.

Any defects or combination of defects which render the hand brakes inoperative shall constitute a violation.

Equipping Foreign Cars with Safety Appliances

Close attention is essential in the matter of giving proper attention in the equipping of cars with safety appliances, both foreign and system cars. Whenever system cars are loaded and it is found they are not equipped with safety appliances, if routed to some foreign railroad, the routing

and destination should be ascertained in order to take the matter up with the foreign railroad to have them equip cars belonging to this road. It is necessary also to equip foreign cars on our railroad, rendering bills against the owners for the expense we are put to. System cars, not equipped, must also be followed to destination points on the railroad and equipped when empty. Cars stencilled as equipped and found actually not so provided, if loaded, are to have the stencilling painted over, if empty, the cars shall be equipped at the owner's expense.

Side and End Doors and Side Door Protection

Doors should be carefully inspected to see that the bottom door guides are in place and tight to prevent pilfering from the car. Door locks and hasps should be in proper condition and in place so that the doors can be properly fastened and sealed. Doors, either top or bottom hung, should be in proper condition and properly secured in place and arranged to close tightly to prevent admission of elements or sparks that would damage freight. Doors on gondola and hopper cars need careful inspection to see that they are in operative condition and close tightly and that the operating mechanism will permit the doors to be closed and locked in such a way that they will not open, to prevent loss of lading.

One of the greatest difficulties with side doors is the prevailing lack of attention to the application of suitable protection in the doorway. It is not reasonable to suppose that cars loaded with bulk vegetables such as potatoes, or shipments in sacks such as flour, sugar, peas, beans, coffee, etc., or paper in large rolls, piled vertically or longitudinally, or commodities in barrels, cases or otherwise, will make a successful run without damage and loss, unless some consideration is given the consistency of trying to hold the lading, which is so apt to shift on account of train and yard movement inside of the car, with the single layer of boards composing the door itself, when a massive side construction in the car body is necessitated for this same purpose. Doors which become bulged bind and interfere with line clearances causing tremendous damage aside from dislocating the doors themselves, ruining adjacent equipment and exposing shipments subject to loss. In this way doors become inoperative and as a result shippers tear them loose with claw bars. Much can be done by interesting shippers in this direction, and if properly handled and the case is made plain to them, their co-operation is obtained.

At interchange points the strictest watch is necessary. Redress must be insisted on from connecting lines for any failure on their part in this regard. This does not mean that it is desired to have the whole opening closed up inside of the doorway. In the case of paper stock in rolls standing vertically, a 1½-in. by 8-in. strip across the doorway, about three quarters of the way up the roll, will keep the lading from doing any damage to the door and the same is true of barrels. Doors should never be spiked to the car frame and care is required to see that shippers refrain from this practice, using suitable wooden slats if the door needs fastening. On loaded cars, inspectors should always be certain that door caps, and stop and spark strips are in good order to avoid the elements entering the car causing damage, and should also see that door guides, track, hasps, rollers, hinge pins and fasteners are all secure and in place. In the case of refrigerator cars, they should see that the side doors fit tightly in place to avoid perishables becoming destroyed, also special care is necessary in the case of loaded cars of stock.

Threshold Plates

On system cars the use of threshold plates is not desired, therefore, cars receiving Class A, B and C repairs are to have them removed and reclaimed for useful purposes.

Roofs for Freight Cars

Roofs of all cars on repair tracks must be inspected and if metal roofs or double board plastic roofs have outside

boards loose, the loose nails must be drawn and the boards renailed with two nails staggered in each board at each purlin, side plate and ridge pole. In renailling care must be taken to use proper sized nails, so that metal roofing will not be punctured, the correct size being $2\frac{1}{4}$ in. No. 8 barbed wire. All nail holes left open after renailling are to be carefully and properly filled with "Sarco," "Bako" or other suitable material to prevent leakage.

Where bolts are employed to hold the roof structure or roofing in place, all bolts are to be tightened up through the ridge pole, carlines, running board brackets, etc., and have nut locks or lock nuts applied to prevent the structure from again becoming loose. Where suitable means are not available for holding the nuts in place, either through lack of material or because of the nature of the repairs, the threads of the bolt should be cut with chisel to prevent the nuts coming off.

When metal roofs are damaged in wrecks care must be taken to save all metal parts that can be used from cars destroyed. When cars are not destroyed, all parts must be placed in the car to which they belong. When cars damaged in wrecks are to be burned, serviceable metal roofs or parts must first be removed. When condemned cars are to be burned or torn down, serviceable metal roofs or parts of same must be carefully removed and kept for further use.

Wooden running board saddles must be secured to the ridge pole by two $4\frac{1}{2}$ in. No. 18 screws and at the ends by two $4\frac{1}{2}$ in. No. 18 screws. Running boards, when loose, must be secured in place by $2\frac{1}{2}$ in. No. 16 screws, two per board at each crossing.

In addition to the repair track inspection and running inspection, the inspection at terminals must include the roof, with handholds, brake shafts and attachments, brake step, etc., and at points where there are shops, and it can be so arranged, men should be regularly assigned to renaill roofs and secure running boards and saddles and fasten roof handholds in freight car yards. All roof handholds must be tested by hand or with a bar when on repair tracks, and if not perfectly secured they must be refastened and secured by bolts through solid wood. One longitudinal running board is required and cars with outside metal or all metal roofs two latitudinal extensions. Longitudinal running boards shall be not less than 18, preferably 20 in. in width. Latitudinal extensions shall not be less than 24 in. in width. Running boards are to be located the full length of the car, at the center of the roof. On outside metal roof cars there shall be two latitudinal extensions from the longitudinal running board to the ladder location, except on refrigerator cars, where such latitudinal extensions cannot be applied on account of ice hatches.

Running boards are to be continuous from end to end and not cut out or hinged at any point; provided, that the length and width of running boards may be made up of a number of pieces securely fastened to saddle blocks with bolts or screws. The ends of longitudinal running boards shall be not less than six, nor more than ten inches from a vertical plane parallel with the end of the car and passing through the inside face of the knuckle when closed with the coupler horn against the buffer block or end sill, and if more than four inches from the edge of the roof of the car, shall be securely supported their full width by substantial metal braces. Running boards shall be made of wood and securely fastened to the car by bolts or screws.

Metal roofs when furnished in accordance with separate instructions, must be applied promptly and properly. Roofs of cars should be maintained in good condition to insure proper protection of contents and avoid damage claims.

Air Brakes

Air brakes should be examined, cleaned and tested in accordance with the rules governing same. Hand brakes should

be operative and capable of holding cars in switching and on grades in addition to meeting the Safety Appliance Laws. Air and signal hose should be in good condition and not more than two years old in the principal trains, gaskets should be examined for tightness to avoid any possible leakage. All piping should be free from abrasions. All rods should be free, full size and prevented against knocking and causing wear or annoyance to passengers in service. All brake rigging parts should stand at least three inches clear above the top of the rail. All cotter pins should be in place and properly spread to prevent being lost. All pipe clamps are to be tight and the location of piping on the ends of cars is to be such as to avoid any buckling or cramping of air or signal hose when connected up.

Couplings for air and signal hose are to be in good order, piston travel to be normal, about seven inches, and all brakes to be operative unless a defect card is wired to the crossover piping, stating the trouble and where found such defects to be remedied before the train departs, if possible, without causing delay and wire advice to be sent forward to the first principal repair station to prepare to remedy the trouble in case the defect cannot be handled locally. Retaining valves must be known to be in proper position. If the train line on passenger cars is broken or defective special combination couplings may be used as found in all standard station boxes, so as to run the air supply through the signal line temporarily until repairs can be made. All passenger car brake cylinders and slack adjusters are to be cleaned every six months, dirt collectors, triple valves, retainers and high-speed valves should be cleaned every three months. Inspectors will watch this closely and keep their foremen advised of any irregularity regarding this.

Before departure of all trains inspectors should satisfy themselves that the brakes have thoroughly released to avoid slid flat and burst wheels. Slack adjusters should be maintained in such a way as to provide about $\frac{3}{8}$ -in. initial shoe clearance on all wheels.

Specification Covering Installation of Air Brake Equipment on Freight Cars

Brake Cylinder and Auxiliary Reservoir.—The cylinder and reservoir must be attached substantially with metal supports having ample strength to avoid deflection during brake applications, with a cylinder pressure of 70 lb. They should be secured with bolts fitted with double nuts or approved lock washers and the bolt heads prevented from turning. Washers must be applied between the brake cylinder and auxiliary reservoir bolting flange and their supporting brackets where necessary to avoid strains in the cylinder or reservoir when the supporting bolts are tightened.

The brake cylinder should be so located as to permit easy removal and replacement of the brake piston. This requires sufficient clearance to permit the piston and non-pressure head to be moved outward horizontally 15 in. The lever guide for the cylinder end of the cylinder lever is to be so located as to provide ample room for removal and replacement of the brake piston.

Release Valve.—The release valve should be installed in the top of the auxiliary reservoir and arranged for operation with $\frac{3}{8}$ in. rods to each side of the car.

Brake Piping.—The brake pipe must be $1\frac{1}{4}$ in., with standard weight pipe nipples not less than 10 in. long at each end. The M.C.B. standard is 10 in. Angle cocks must be located as per M.C.B. standard. Pipe near the angle cocks and elsewhere is to be secured by approved clamps that will prevent vibration or movement otherwise.

The branch pipe from the main brake pipe is to be reduced from $1\frac{1}{4}$ in. to 1 in., with a nipple not over 3 in. long at connection to the triple valve, and to contain two 90-degree pipe fittings so placed as to permit flexibility to compensate for reasonable variations in the location of the brake pipe

tee and triple valve. A substantially true bearing of the gasket face of the union on the triple valve must be insured, so that the connection may be made without producing undue strain on the union. If the branch pipe passes through the center sill, the sill must be slotted so that the branch pipe union can be moved sufficiently to permit of easy removal of the triple valve.

The cutout cock handle is to turn upward to close, and if practicable should be located so that it can be seen from either side of the car.

The centrifugal dirt collector is to be placed between the cutout cock and triple valve, so located that the drain plug can be readily removed. The raised arrow on the cock is to point toward the triple valve. The bottom of the drain plug must not be lower than the bottom of the triple valve.

Retaining Valve and Pipe.—The retainer and pipe must be located securely in a vertical position on the end of the car near the brake staff and with sufficient clearance for the removal of the cap. Where the pipe passes through the hand brake step, the step should be slotted sufficiently to permit of springing the pipe back enough to remove and replace the retaining valve. On cars having drop ends, the retaining valve is to be accessibly located on the side of the car near the brake staff end.

The retainer pipe is to be connected to the triple valve with a short section containing a 90-degree bend, each leg preferably six inches long, with the union on the end of this bent section. The outer end of the bent section is to point vertically upward, or approximately so, in order to provide the necessary flexibility. The pipe is to be clamped about six feet from both the triple valve and retaining valve and at intervals of about six feet between, the clamps to be substantial and solidly secured. One union only is to be used, unless it is impracticable to so install the valve.

Piping, General.—Pipe ends are to be reamed to full size after cutting, and pipes hammered and blown out before erecting. Where it is absolutely necessary to install unions in the brake pipe they must be accessibly located for maintenance.

Pipe Fittings.—All piping is to be assembled with as few fittings as practicable, and all fittings used, with the exception of those regularly included in the air-brake schedule, are to be "extra quality pipe fittings for railroad air brake service," as listed in the Westinghouse Air Brake Company's Special Publication, No. 9021. Unions are to be brass-to-iron seat, taper joint type.

Braking Power.—The brake rigging is to be designed to produce braking power equal to 60 per cent of the empty car weight, based on 50-lb. cylinder pressure, excepting for cabooses, which will be braked at 45 per cent. The value of an eight-inch cylinder at 50-lb. pressure is 2,500 lb., and of a ten-inch cylinder 3,950 lb.

Note.—While the M.C.B. standard requires the use of the ten-inch equipment with cars exceeding 37,000 lb. empty weight, the more uniform piston travel maintained, with less expense and delay with lower total leverages, warrant the use of the ten-inch equipment on much lower empty weights.

Brake Beams.—Brake beams must have sufficient strength to carry a force equivalent to .21 times the empty weight of the car without deflecting more than .07 in. (the M.C.B. deflection limit). Brake beams are to be suspended at the M.C.B. standard height from the rail (13 in.). The suspension is to be from the rigid portion of the truck frame with brake beam hangers of the U-type, made of material not less than 7/8 in. in diameter and not less than 8 1/2 in. long, center to center, preferably much longer.

The spacing of the brake heads is to be according to the M.C.B. standard, that is, 60 in. from center to center of brake heads, with a maximum allowable spacing of 60 1/8 in. and a minimum of 59 7/8 in.

The brake beam hanger is to be attached to the truck frame at a point that will prevent the hanger from assuming an angle to a line through the centers of the beam and journal, which will cause excessive toggle or wedging action under brake application when brake shoes and wheels are of minimum dimensions.

Strength or Brake Rigging.—All brake rigging is to be designed to carry the forces resulting from a brake cylinder pressure of 70 lb. without exceeding the M.C.B. stress limits, which are:

Levers	23,000 lb. per sq. in.
Rods	15,000 lb. per sq. in.
Jaws	10,000 lb. per sq. in.
Pins	10,000 lb. per sq. in.
Pin bearing (on projected area).....	23,000 lb. per sq. in.

The value of an eight-inch cylinder at 70 lb. is 3,500 lb. and of a ten-inch cylinder 5,530 lb.

The hand-brake rigging is to be designed to meet these requirements, and with 1,500 lb. pull on the hand-brake rod, except where a geared hand brake is employed, in which case the forces to be carried will be increased in proportion to the hand brake gear ratio.

Levers, General.—All pin holes in brake levers must be on the longitudinal center line. Levers must not be bent or offset sidewise. Both the front and back cylinder levers are to be as long as practicable and so designed and located as to prevent a lateral thrust on the push rod when the brake is applied. Live and dead truck levers are to be in the same ratio with as low a proportion as practicable and in no case to exceed four to one, i. e., produce more than four pounds force on each brake beam for one pound exerted on the top of the live lever.

Slack Adjustment.—With cars having deep side sills a hole must be provided through which to observe the piston travel. Slack adjusting fulcrums and bottom rods must be provided with a sufficient number of holes properly located to permit of accurate piston travel adjustment for new shoes and wheels as well as for shoes and wheels of minimum dimensions and at the same time must permit of maintaining levers at substantially right angles to the rods under brake application with eight-inch piston travel.

All pins should be removed from pin holes in slack-adjusting fulcrums to permit free movement of levers. The hand slack adjuster is to be so attached to the trucks that there will be no toggle action when the dead levers are in their closest position to the truck bolster.

Rods.—Brake rods should be of such length as to produce, with an emergency application from 70 lb. brake pipe pressure, piston travel of six inches to seven inches, the truck levers being attached to the inside holes of the slack-adjusting fulcrums and bottom rods.

With the brake applied and eight inches piston travel, the top rods and cylinder rod should be of such length that the cylinder levers will stand at a right angle to the longitudinal center line of the car, and the length of the bottom rod should be such that the live truck lever will not pass beyond a right angle to the top and bottom rods. Sufficient clearance should be provided between the top rods and the axles to insure against rods being cut.

Lever Guides.—Sufficient clearance must be given to permit free movement of all levers to the positions they will assume when the brake shoes and wheels are of minimum or maximum dimensions and the piston is in release position or its travel is 12 in.

Brake Pins and Pin Holes.—These parts are to be strictly in accordance with M.C.B. standards.

Rail Clearance.—The brake rigging is to be so installed that with the maximum allowable tire turning, wear of journal bearings, etc., the brake rigging will clear the rails not less than 2 1/2 in.

(To be continued.)

REINFORCING TOP CHORD ANGLES ON GONDOLA CARS

BY NORMAN McCLEOD.

Owing to the bulging of the sides of steel freight equipment cars, especially those of the gondola type, it has been found necessary on certain cars to reinforce the top chord by applying a 4-in. by 4-in. by 1/2-in. steel angle, as shown in the cross sections in Fig. 1. These reinforcing angles are in one piece and are drilled and riveted at intervals of about eight inches. Ordinarily it required two men to do this work, but the device shown on the accompanying drawings makes it possible for one man to do it.

The device consists of an oak seat (on which the operator

sits), to which is bolted a wrought iron vertical member in the form of a yoke. From the yoke is suspended the air motor drill, the arms being supported by two hooked 1/2-in. rods. These arms are provided with two springs, which, as

General Arrangement of the Drill Support

the drilling progresses, are in tension. After the drill has passed through, these springs draw the drill out of the hole automatically as the feed screw is backed off, since the springs keep the drill feed screw center point always up against the lower end of the adjusting screw, on the end of which is a female center to receive it. Thus the springs prevent a sudden dropping of the heavy air drill, which might injure not only the machine but also the operator.

The hooks on the side of the seat engage the downward pointing leg of the angle being drilled and with the brace beneath the seat, prevent the device from moving out of place. In using this device the operator does not leave his seat, but is able to slide the frame along from one hole to another.

QUESTIONS FOR THE CAR INSPECTOR

Every car inspector must be familiar with the Rules of Interchange, the Loading Rules and the Safety Appliance Rules, and daily he is confronted with a variety of problems involving all of these codes. Some of these recur so frequently that their solution becomes almost automatic, but others come up only occasionally and sometimes in such form that the proper action is in doubt. A study of the following questions and answers may help in the solution of some of these questions when they next present themselves.

Interchange Rules

Question—For what purpose is the billing repair card used?

Answer—A billing repair card must be made out when repairs are made to foreign cars.

Question—What general practice should be adopted when making repairs to cars?

Answer—Repairs should be made promptly and should conform in detail to the original construction except as provided in Rules 17, 18 and 87.

Question—What is the standard height of couplers?

Answer—For empty cars, 34 1/2 in.; for loaded cars, 33 1/2 in.

Question—How should coupler heights be measured?

Answer—From the top of the rail to the center of the coupler head.

Question—Who is responsible for advertisements on cars in interchange?

Answer—The delivering company is responsible.

Loading Rules

Question—What rule should be observed in selecting flat cars to be used as idlers?

Answer—Flat cars of wooden construction must not be less than 80,000 lb. capacity, except that 60,000 lb. capacity may be used if equipped with inverted truss or steel centre sills.

Question—What rule governs the width of overhanging load on single cars?

Answer—Rule 11 of the American Railroad Association loading rules. The width of overhang should not exceed the following dimensions:

Length of overhang		Width of Load	
Ft.	In.	Ft.	In.
9	0	9	5
10	6	9	2 1/2
12	0	9	0
13	6	8	9 1/2
15	0	8	7
16	6	8	4
18	0	8	1
19	6	7	0
21	0	6	4
22	6	5	8
24	0	5	0

If the height of the load exceeds 12 ft., subtract 2 in. from the given width of load for every inch of height in excess of 12 ft.

Question—How is overhang measured?

Answer—From the center of the truck to the extreme end of the overhang.

Question—What specifications are quoted for stakes, clamping pieces, bearing pieces and braces?

Answer—They must be good, straight grain lumber free from knots that impair the strength, preferably hard wood lumber. They may also be rolled or built up steel sections of equal strength. Care should be taken to see that stakes do not spread at the top while cars are being loaded. In no case should the width of the load exceed the width of the car.

Question—What is the proper size for stakes?

Answer—Unless otherwise specified, stakes for flat or gondola cars with sides less than 30 in. high must be 4 in. wide by 5 in. deep or green saplings 5 in. in diameter at the center. For gondola cars 30 in. high or over, stakes may be 4 in. wide and 4 in. deep or green saplings 4 1/2 in. in diameter at the

center. All stakes must be properly tapered at the ends to fit the stakes pockets and extend through and completely fill the pockets.

Question—Is it permissible to place stakes on the inside of gondola cars?

Answer—Yes, providing the sides of the car are 30 in. high or over. Stakes must rest on the floor and be wedged substantially to the car sides by the lading.

Question—What method should be followed when reporting dimensions of stakes?

Answer—The figure representing the width should be reported first and the figure representing the depth second. Width is measured parallel to the side of the car and depth at right angles to the side of the car.

Question—What should be done when the dimensions of stakes are smaller than the stake pockets?

Answer—Wedge the stakes tightly in the pockets by driving in wedges from the top and nailing them to the stakes. Unless the wedges are nailed to the stakes they will work out when the cars are in motion.

Question—How should stakes be fastened to prevent spreading at the top?

Answer—When boards are used there must be two boards for each pair of stakes. The boards should not be less than one inch by five inches and securely fastened at the ends to the stakes by not less than three tenpenny wire nails. When wire is used, unless otherwise specified, it must be equal to six strands or three wrappings of good $\frac{1}{8}$ -in. diameter wire. Wire must be secured to prevent slipping.

Question—Is it permissible to substitute wire heavier than $\frac{1}{8}$ -in. in diameter?

Answer—Yes, $\frac{3}{16}$ -in. wire may be substituted, in which case two strands or one wrapping of $\frac{3}{16}$ -in. wire will be equivalent to six strands or three wrappings of $\frac{1}{8}$ -in. wire. Four strands or two wrappings of $\frac{3}{16}$ -in. wire will be equivalent to ten strands or five wrappings of $\frac{1}{8}$ -in. wire.

Question—On cars offered in interchange, who is responsible for the application of the additional stake pockets necessary to apply stakes in accordance with specifications?

Answer—The delivering road is responsible and if applied by the receiving road the expense may be billed against the delivering road.

Safety Appliance Rules

Question—Is it permissible to weld uncoupling levers?

Answer—The safety appliance laws do not prohibit welding of uncoupling levers but the American Railroad Association, Section III—Mechanical does not approve of, and prohibits such practice.

Question—Is there a specified design of uncoupling lever?

Answer—No. Any efficient design may be used, either single lever or lever extending the full width of the car. On tank cars without end sills the uncoupling lever must not be less than 42 in. long.

Question—Where should uncoupling levers be located?

Answer—One on each end of the car. If the single lever is used it must be placed on the left side of the end of the car when facing the car.

Question—What further is specified relative to the location of uncoupling levers?

Answer—Handles must not be more than 12 in. from the side of car, preferably 9 in.

Question—What is the proper length of uncoupling lever handles?

Answer—Not more than 15 in. nor less than 12 in. long.

Question—How much clearance must uncoupling lever handles have?

Answer—Handles must extend at least four inches below the bottom of the end sill, or be constructed so as to have at least two inches clearance.

Question—What is the proper length of the center lift arm?

Answer—Not less than 7 in. long. The center of the eye in the end of the lift arm must not extend more than $3\frac{1}{2}$ in. beyond the center of the eye in the coupler lock lift.

Question—How should rocking or push down type uncoupling levers be arranged?

Answer—They should be applied so that the handle will not be less than 18 in. from the top of the rail when pushed down to the position where the lock lift releases the knuckle. A stop must be provided to keep the inside section in position in case of breakage.

AN UNUSUAL HOT BOX

Journals burned or twisted off due to overheating are of such common occurrence that they cause little comment, but when a journal runs without breaking off until the diameter is reduced from 5 in. to $2\frac{3}{4}$ in. and the length increased from 9 in. to $13\frac{1}{4}$ in., the circumstances are sufficiently out of the ordinary to deserve some notice.

Some time ago, when looking over a train from Kansas City, an inspector on the St. Joseph & Grand Island at St.

Dimensions of the Journal When Removed

Joseph, Mo., discovered a journal with the end sticking out of the box. The journal was a cherry red and all the babbitt had melted out of the brass, yet the journal was not bent, although the car was loaded. The train crew stated that they had moved this car from Kansas City to St. Joseph, a distance of 61 miles, without experiencing any trouble and that no attention had been given the car between the two points.

On removing the wheels the axle was found to have been

The Elongated Journal, With and Without the Journal Box

drawn down as shown in the sketch. The 5-in. by 9-in. journal had been lengthened $4\frac{1}{4}$ in. and tapered from 5 in. at the shoulder outside of the wheel and just inside of the collar down to $2\frac{3}{4}$ in. in the center of the journal, almost as perfectly as if it had been turned to this shape in a lathe. It was drawn out without any loss of metal, as the weight was the same as that of a second hand axle after it was removed and weighed. Both ends of the brass were worn off until there was only 5 in. of the 9-in. brass left, which had its bearing on the smallest part of the journal.

WELDING A WORN DRIVING WHEEL FLANGE

The value of oxyacetylene welding is becoming more and more evident in every industry where the repair of machinery is necessary. One of the recent examples of the economical advantages of the process is shown in the repair of a worn driving wheel flange on a passenger locomotive of one of the large railroads. The flange in question was on one of the rear driving wheels and had been badly damaged by contact with a defective brake shoe.

Ordinarily in a case of this sort it is good shop practice not only to turn down the worn tire, but the other tires of the locomotive as well in order to reduce all of the wheels to the same diameter; or, if they have already been worn to the limit, to replace them with new tires. This work is expensive. Usually a week is required to remove, machine and replace driving wheels. A longer time is necessary where new tires are applied.

In this particular case the tires had received their last

The master mechanic in charge of the shop decided that the worn flange could be built up by their Airco welding torches and accordingly set to work to repair the flange, leav-

Value of six 72-in. diameter driving wheel tires with a period of life equivalent to that of the six worn tires on the locomotive; cost of replacement, etc.....	\$625.00
Oxygen	\$5.00
Acetylene	8.75
Welding rod	3.00
Labor of welder and two helpers.....	22.64
Total cost of welding.....	\$39.39
Scrap value	90.00
Total cost of repairs.....	129.39
Net saving	\$495.61

ing the driving wheel in its usual place under the engine.

The side rods were removed, and rollers ordinarily used for setting valves were placed under the wheels in order to revolve them as the welding work progressed. After the weld

Welding the Worn Flange Without Removing the Wheels from the Locomotive

turning, making it impossible to repair the flange in this way. To renew the wheels with an entire new set of tires would have meant the waste of about six months' wear still obtainable from the old tires.

was finished the flange was ground with a portable surface grinder.

The work took twenty hours, the locomotive being put back on its regular run at the end of that time. Several

days of locomotive service were saved, not to mention several hundred dollars' labor required if the wheels had been dropped. Cost details are shown in the preceding table.

The welding of the tire took place more than five months ago, and the locomotive has been in continuous operation

The Appearance of the Flange After Welding and Grinding

since that time. When inspected recently it was found that despite the strain to which this part of the wheel is subjected, the welded flange showed only a normal wear.

TOOL HOLDERS FOR MACHINING PACKING RINGS ON A BORING MILL

BY E. A. M.

An attachment to a boring mill, which makes it possible to perform three operations simultaneously, is shown in the drawing. With this device packing rings can be turned, bored and cut off at one setting, thus increasing the capacity of the mill and materially reducing the cost of production.

The boring and turning tools 5, which are made of one-

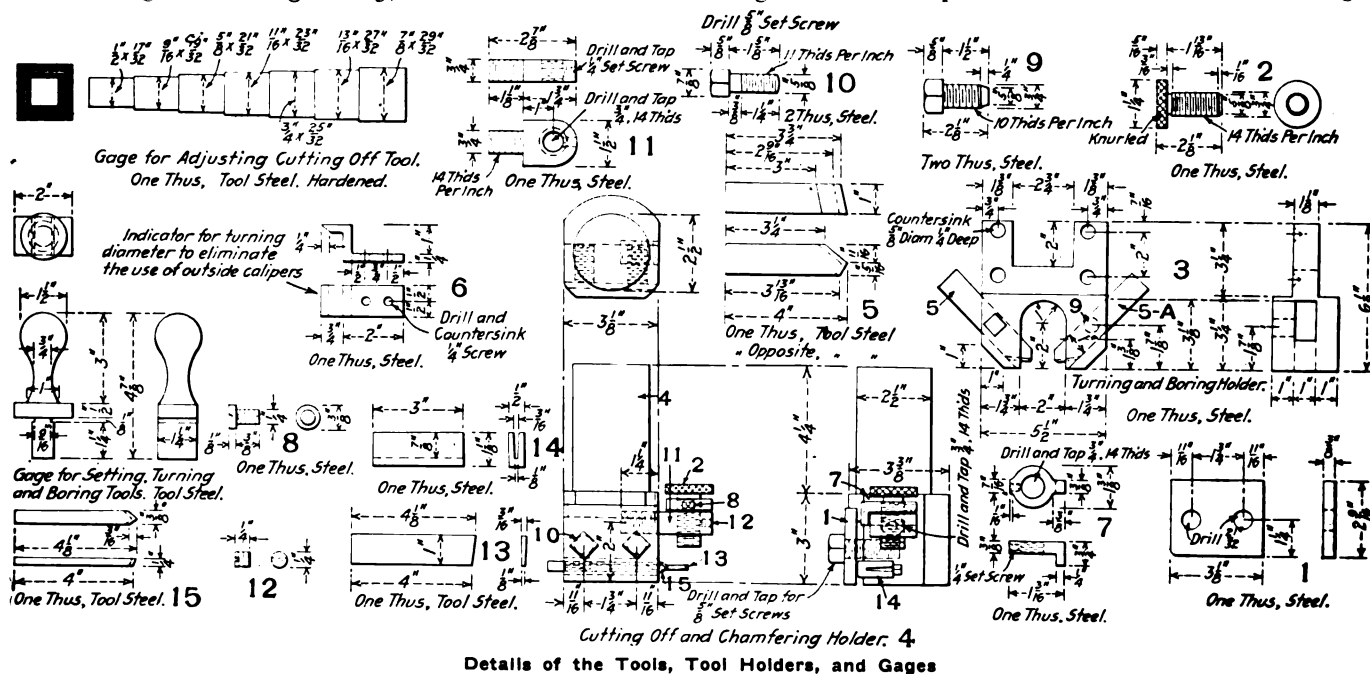

size of ring desired. The adjustable guide 11 is screwed into the side of the holder 4, and in turn holds in place the screw 2, which is screwed down through the holes in the guides 7 and 11, and is locked in position by the small screw 12, which screws into the end of the guide 11, and by the screw 8, which screws into the guide 7. By this arrangement the holder 4 also acts as a lock on the cutting-off tool holder. The screw 2 reaches to and rests on the part to be machined and the cutting-off tool is then properly set to produce the

Boring Mill With the Holders Applied

After one ring is cut off the tool is lowered the thickness of a ring and another one cut, repeating the operation as often as desired or the stock will permit.

The steel piece 6 acts as an indicator for turning the required diameter of ring and eliminates the necessity for using an outside caliper. As will be seen in the drawing of

Details of the Tools, Tool Holders, and Gages

inch square tool steel, are secured in the holder 3 by the set screws 9. The chamfering tool 15 fits into the narrow part of the slot in the holder 4, and the cutting-off tool 13 is placed in the grooved holder 14, which is held in place in the holder 14 by the plate 1, which is secured to the holder 4

the boring mill, this indicator 6 is fastened on the boring head and a number of lines are scribed on the cross rail of the machine to provide for convenient and accurate adjustment of the indicator. Gages for setting the boring and turning tools and for adjusting the cutting-off tool also are shown.

THE LABOR SITUATION TODAY AND TOMORROW*

Creation of an Incentive Will Stimulate Production; More Conciliation and Optimism are Necessary

THE labor problem today is universal and there has been so much thought given it and so much said regarding it that it is difficult to do more than reiterate salient facts which have crystallized out of the general problem.

A situation confronts us today unlike any before experienced, and to counteract its effect it is essential that its significance be fully appreciated, as it will call for the full efforts of all who believe in democracy and the maintenance of democratic ideals. The influence which is now being brought to bear to undermine the social structure of the world is making itself felt through many other channels than labor, but it has undeniably had a tremendous effect on labor conditions.

During and following the crisis through which the world has just passed, the laboring man, forced by the high cost of living, sought to better his position, and, influenced by propaganda, he directed his efforts not only toward increased wages but on a reduction in working hours, and the results are fast leading to another and even greater crisis. When hours decreased, production decreased; the unit of production cost more to create and the employer was forced to increase his price to the consumer in order to maintain his income, with the result that the value of the dollar depreciated proportionately and the situation was relatively the same as prior to the initial change. This decrease in production, however, had another effect. It required that more labor be employed to obtain the same output, and the natural result is the present shortage of labor.

It is recognized that it is not possible to realize the same production in the eight as in the ten-hour day, but had this been possible it would not have been necessary to increase prices, the cost of living would not have increased, the value of the dollar would not have decreased, and the world in general, but the laboring man in particular, would have been greatly benefited. As long as wages are advanced and production decreases or even remains the same, the cost of living must necessarily increase and the circle becomes endless. It is absolutely impossible for the laboring man to make headway against the cost of living by the methods that are being followed today. The one and only relief is increased production. Germany has already realized this fact and her workmen have voted for the eleven-hour day in order that production may meet the demands and again permit them to wage the fight for commercial supremacy. How this increased production is to be obtained in America, however, is the real problem of the present time.

It is apparently necessary first to stimulate production by creating an incentive to produce. We cannot today outline a method that may be pronounced "best," but some manufacturing concerns are now trying methods which will, no doubt, create an interest on the part of the employees in the success of the business. It will probably be very difficult to apply any plan that is being tried at the present time to the railroads on account of the diversity of work and the extent of the territory they cover, but out of the numerous plans that are being tried one should be evolved which will gain the desired results, and the mutual efforts of employers and employees along these lines can, without question, create a successful plan.

In connection with any campaign to increase production it will be necessary to undertake a thorough and systematic

education, applied particularly to those who have come to us from foreign countries and who speak our language but poorly, and who do not understand our institutions and our ideals. Their very misunderstanding creates fertile soil for the growth of radical ideas that are the subject of a systematic and universal propaganda today.

If the evil is to be entirely overcome it will require the combined efforts of every loyal citizen of America, it will require that citizens exercise fully and properly their right of franchise; that responsible, reasonable men may be elected to offices in our city, state and national government. While it might be supposed that this is universally recognized, the fact remains that throughout the entire United States educators are being forced to leave their stations and accept more lucrative positions in order to meet the present increased cost of living, and our city governments are not taking steps to remedy this evil. Education is the best antidote for radicalism, though without doubt it will not be effective in all cases. Steps are under way now, however, to cope with the radical leaders through proper legislation, and such legislation will probably be made effective in the near future so that our immediate attention might be turned to the followers rather than to the leaders.

By education is meant the broad sense of the term, not merely class-room teachings of the English language, but instruction in American institutions, ideals and the spirit of fair play, and it is suggested that the man on the ground, that is, the supervisor who comes in closest contact with the working man, can accomplish far more in this respect than any one else. By keeping in close touch with his men; providing for their needs; listening patiently to their grievances; always applying discipline when necessary, but only when necessary, and then only after the man concerned has been given full opportunity to be heard and such discipline administered with the idea of saving instead of losing the man, he will gradually gain their full confidence and respect and his troubles from the labor standpoint will proportionately diminish.

There is a feeling on the part of a great many individuals that unionism alone is responsible for the present situation, and it is suggested that a more optimistic view of relationship with labor organizations and co-operation with them along reasonable lines will be quite effective in removing some of the present difficulties and eliminating some of the present feelings. Conciliation will gain more than opposition. The real cause of this feeling is, no doubt, the influence being exerted by the radical elements that constitute a small minority of present-day labor organizations, just as this influence is also being exerted in our political life. It can be counteracted most effectively by the older and more reasonable members taking an active part in affairs and exerting their influence to counteract the ill effect, just as our political life, the influence of the radical element may be eliminated by the full exercise of franchise on the part of the loyal citizens of the country.

When we are able to free ourselves of the radical elements, to properly educate others, to increase our production to meet or exceed present-day demands, to reach the point where the employer and employee will meet and discuss with reason their difficulties there will be little left of "the labor problem." This may appear to be an extremely optimistic view of the situation and may further appear to be so far in advance of present-day conditions as to be Utopian, but it is

*From a paper presented by Frank H. Hardin, before the Central Railway Club, March 12, 1920.

suggested that optimism is the prime requisite in the battle and that pessimism is always defeated before the fight begins.

Discussion

D. R. MacBain (New York Central) offered some suggestions for supervising officers. He stated that although the task of the supervisors seems hopeless, optimism is needed. He ascribed much of the present difficulty to lack of personal contact and the tendency on the part of the local officers to evade their responsibilities. To show that socialistic rule made conditions worse for the workers he cited the fact that Russian workmen are compelled to labor 13 hours, seven days a week. The dissemination of such information was urged by Mr. MacBain as a means of combating the tendency toward bolshevism.

W. O. Thompson (New York Central) argued that the keynote to the situation was getting closer to the men and gaining their confidence.

W. Flynn (Michigan Central) expressed the opinion that the labor problem is not insurmountable and that the solution lies in education and optimism.

F. C. Pickard (D. L. & W.) stated that the roads were now going through a transition period and the tendency is in the right direction. In his opinion, troubles could be minimized if an effort was made to adjust grievances with more promptness.

J. J. Rossiter (New York, Chicago & St. Louis) laid the blame for the present unrest on the radical element, whose slogan is higher wages and less work. As long as this propa-

marked improvement would be effected. He suggested that the more general use of machinery would aid in increasing production.

F. W. Brazier (New York Central) expressed the opinion that production has now decreased to the danger point. The present labor organization discourages direct contact between the officers and the men, and the incentive for production has been removed under present rules. The big problem is to restore the morale. The only salvation is in more production, and conciliation is needed to bring results.

C. L. McIlvaine (Pennsylvania) cited some examples of high production under present conditions, and stated that it is a mistake to condemn men as a whole for the acts of a few. Labor has suffered because of poor leadership, but the tendency now was to break away from the radical element, and he thought that a great improvement could be effected if the management did not antagonize the men.

HOSE STRIPPING MACHINE

By R. S. H.

A machine for stripping the connections from old or worn out air hose is shown in the drawing. This device is operated by compressed air, controlled by a four-way valve, and is being used in place of hand methods in the scrap reclaiming plant of a Western railroad.

The construction of this machine is comparatively simple and it does the work quickly and efficiently. The hose is

Assembly and Details of the Hose Stripping Machine

ganda is heeded it will be impossible to bring the cost of living down. Although strikes have recently been called off, it is doubtful whether the men are now giving fair production. Mr. Rossiter believed the remedy lay in the overcoming of the radicals by the conservatives in the railway labor organizations.

L. D. Gillet (Dominion Railway Commission of Canada) expressed the opinion that in the labor situation at present bolshevism of the worst type must be contended with, and inwardly many are viewing the problem with extreme pessimism. Labor has learned the strength of organization, and the situation is made worse by the fact that a small number of men who have been in the army have become agitators. One man of this type can have a bad influence on a hundred others.

W. A. Buchanan (D. L. & W.) submitted that if the principles brought out in the paper were applied every day a

placed on the two blocks A with the hose connections slipped over the jaws B. The top cylinder is then filled with air and forces the platen downward, securing the hose firmly in place on the blocks A. This prevents slipping of the hose in case one of the hose connections should be freed before the other. The air is then turned into the lower cylinder, and through the system of levers, operating as indicated by the arrows, strips the connections from the hose. The small cylinders at each end of the bench act as cushions and absorb the shock when the connections suddenly pull out of the hose.

A machine of this type can easily be constructed and the speed and economy of operation have demonstrated its value over hand methods by a considerable reduction in the amount of labor required for the work and saving in the time required to strip a given number of hose connections from old and worn out air hose.

GRAPHIC PRODUCTION CONTROL IN RAILWAY SHOPS*

Production Department Coordinates the Work of All Departments in Angus Shops of the Canadian Pacific

BY E. T. SPIDY

Production Engineer, Angus Shops, Canadian Pacific

IN the management of any industrial plant the author has become convinced through plain experience that apart from the personality of the management directing affairs and the regular accounting system there is a great need everywhere for the placing of facts in such a manner that the condition of affairs to-day can be seen quickly in their true relation to the policy of the management.

We are all more or less accustomed to seeing statistics shown graphically. Their value to show what has happened is of unquestioned value. We are able to see at a glance, for instance, how our expenditure on a certain class of output compares with last year and if we plot on the same sheet the amount of our output we are able to see how the cost has

the foreman can perform them because they concentrate on that particular object only.

Specializing needs no introduction; on our machines and operations we know a specialist can produce more than an all-around man on work adaptable to specializing. We would not think of having the same boilermaker who puts a patch on a boiler roll in tubes, for the same reason specializing applies in management questions. A few concrete examples will show how graphical production methods permit a specialist to perform functions that assist the executive by supplying information that is up-to-date on what is causing delays or what will cause delays.

Locomotive or Passenger Car Repair Costs

The first case is a shop repairing locomotives. The methods apply equally to a passenger car repair shop. The object is to assist all foremen to plan their work so that delays to output are minimized. Analyzing the shop, there are 30 departments, all receiving some part of each engine or car to repair and on each of which rests the responsibility of having that part ready at a certain time when the process of erecting demands it. Based on the road report and a preliminary inspection, the scheduleman and the general foreman of the shop determine that it will require so many days to complete. This period is determined by adding together the time required on all the various detail jobs known. From past experience we have developed a series of schedules from 9

Fig. 1. Chart of the Type Used to Show What Has Happened

varied with the output. Such a diagram as shown in Fig. 1, is a familiar one and needs no explanation.

Let us suppose you have received a statement showing departmental expenses, or a statement of output in which an item shows lower than your expectations or the average. You see a condition that, had you known it was happening, you could have done something to correct, but all you can do now is to investigate and make such changes as your judgment dictates.

After you have received an explanation, censured your man or perhaps replaced him, what guarantee have you that you will not look at an even worse condition next month? The only guarantee you have is your confidence in the man in charge. This confidence I do not for an instant depreciate, because it is your mainstay with the most perfect system, but in this age of specializing would you not be better off and would not the individual departmental head or foreman be better off if you were to supply him with information on expenses or where he stands on his output, or other details, that is "up to the day of looking at it" so that he can control the situation to give you what you want?

Can this be done? It can if you organize to do it. You must assist the foreman by training specialists to perform functions that are at present part of his duties, better than

Fig. 2. The Master Schedule

to 30 days each, one of which is applied to each engine or car as the work demands. The locomotive repair schedules are practically all based on one 18-day schedule, in that on all engines the operations for the first five days and the last seven days are practically the same, the time between being taken up by the department having the excessive or special work to do.

We now come to our first chart which is called a master schedule. The master schedule forms, shown in Fig. 2, have listed down the left side all the controlling detail operations or parts in the sequence in which they must be completed. At the top of the vertical columns each engine or car number is entered as it is taken in the shop, and then by the applica-

*Abstract of a paper read before the Canadian Railway Club, January 13, 1920.

tion of the selected schedule the date it is required completed or delivered is entered opposite each operation. When this is done the second form, called a date schedule, is made out. This is identical with the master schedule except that the days of the month instead of engine or car numbers are placed at the top of the columns and in the column for the date as entered on the master schedule is inserted the engine or car numbers opposite the various operations. By a four color code exactly what has happened is entered on both charts every day, showing whether "on time," "shop late," "material delivery late," or "drawings late" in black, green, red or yellow respectively. At a certain time the schedulemen make a check of all shops, after which they mark up the master and date schedules. Following this they make out from the date schedule, for each departmental foreman, a list of operations due completed to-morrow and include on it, especially marked, all items that are late. This daily "order of work" sheet is delivered to each foreman the night before the day it covers, so that he can plan his work to cover every item. Incidental to this, a list of all late items in all shops is prepared for the general foreman and superintendent in order that they may use their influence to prevent further delays.

We thus have before us a graphic record of the progress of each engine or car showing each delay as it occurs, from which weak points can be seen at a glance. The result is co-operative effort because each department realizes that the management knows what is going on and can measure each man's effort. It makes it unnecessary for foremen to leave their shops to trace material, this being part of the scheduler's duties. When extra work is found necessary, thus setting back the original date of delivery, the change is automatically taken care of by the production department.

OPERATION	1	2	3	4	6	7	8	9	10	11	13	14	15

Fig. 3. The Date Schedule

The net result is a shorter number of days in the shop per unit, the time between jobs is reduced and costs are lowered.

Locomotive or Passenger Car Repair Costs

It is important that we know certain detail costs at current periods. Costs do the shop little good if they come when the job is completed. The method used is suitable for all classes of work where average costs are maintained and used as a base for expenditure. It is not recommended in this form for manufacturing small articles or a quantity product.

Fig. 4 is a graphic representation of current locomotive repair costs. On the left is a scale of dollars large enough to cover the anticipated range. Each vertical column is headed with the engine number; the date it came in the shop and the class of repair is also inserted for reference. By arrangement with the cost department these daily costs are given preference and are supplied the second day after they

are incurred on a special form for the purpose, and on the cost chart a black line is extended daily under each engine to show the total cost to date. In each engine cost column a red cross line is drawn at a point opposite the estimated cost of the job. An estimate is made for each engine, based on an average in the case of straight repairs, as soon as the inspection is complete. Included in this are the allowances necessary in the case of extra or special repairs. Now when an executive looks at the chart he notes particularly those engines that have gone past the red mark and by referring to the engine master schedule he sees what has happened and the progress of that particular engine. He is then in a position to act if his judgment indicates that the cost is abnormal.

It will be noted that short thin black lines extend from each engine cost line at more or less irregular intervals with a number close at hand. These lines are to indicate the amount added each day, the number representing the date. We can thus see whether the labor expended has been irreg-

Fig. 4. Chart for Recording Current Locomotive Repair Costs

ular, or whether it is a steady growth. This is a clear indication of good or bad organization in the shops. Great use can be made of this chart. It shows poor distribution of labor in detail and enables conditions that bring about high costs to be analyzed thoroughly and acted on before the question is asked.

Cost of Manufactured Material

It is desirable to know the efficiency and cost of each order for manufactured material up to date during its progress through the shops. The method described is used by manufacturing concerns, who have found that the way to control costs is in the shop while the job is in progress, and it is applicable to railroad back shop manufacturing.

It consists of a job cost sheet which is kept in the shop office. These sheets are kept in loose-leaf book form and the duties of the cost clerk are to enter in the proper column, from the daily time cards, the costs incurred during the previous day. By noon the cost of each order up to the previous evening should be entered. On each sheet is detailed the standard method of doing the job and the standard time allowed for each operation. This information is obtained from the production department which develops the correct method, working with the shop engineer and the foreman of the department, who at the same time recommend such special jigs and tools as may be deemed necessary. When the order is unusual or rare enough not to warrant making standards for further use, a summary estimate is made up for each operation by the production department in order that a daily check may be kept on the job.

The duty of the cost clerk is to call the attention of the foreman or the party concerned when the cost exceeds the

allowance up to the point in its progress which the order has reached. The foreman is thus kept posted on the cost of each job at all points of its progress, not after it is done and too late for him to do anything about it.

Major Account Expenditure

Fig. 5 is a form used to show graphically a summary of expenditures on major accounts. This type of form was developed by the late H. L. Gantt and used effectively to record progress of airplane and munition manufacture in his work for the United States government during the war.

We want to know how our daily expenditure on each account compares with the allowance for the day, also how

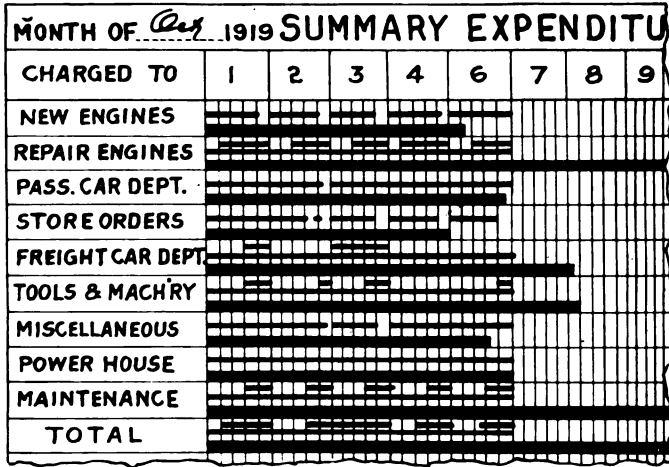

Fig. 5. Current Summary of Major Account Expenditures

our total expenditure to date compares with the total allowance to date on each account. The chart contains one vertical column for each day of the month, over which the date is inserted. On the left hand side the name of each account is inserted. We then calculate the allowance for each working day of the month and enter it for reference on the right hand side of the chart. The distance horizontally between each date column represents 100 per cent of the daily allowance figure, and as the actual expense figures are received, a line is extended across this space equal to the amount actually expended. If this is less than the allowance the percentage of this line will not cover the space, if more than the allowance an extra line over the one covering the space shows how much. Directly under this line representing the daily expenditure is a thicker line which represents summary cost to date. This line is merely extended daily by the same amount as entered under the daily cost column, except that it shows by its total length whether the account is over or under expended to date.

While this sounds somewhat complex it really is extremely simple in operation and furnishes a complete record of how much, when and on what accounts we have over or under expended. The chart is soon readable by any one and shows immediately how closely instructions are being attended to. The idea is one of vast possibilities aside from costs wherever units and summary data is required.

Detail Operation Schedule

Fig. 6 illustrates a method used by the author to plan the work for every productive man and machine in a department. The shop control board contains a separate slot for every man or machine, the identification being placed down the left side. As each order is received by the production department a ticket is made out for each operation equal in length to the time allowed for the operation. The tickets are made on profile paper with 20 divisions to the inch, each division representing one hour. The board is black with

vertical white lines at weekly intervals. In the top slot is located the date strip, showing days of the month for the period covered on the board. All the work for the shop is represented on the board, each operation being located in the proper slot. When material is available each operation from the first to the last is located in its respective slot at the proper date so that time between operations is reduced to a minimum, taking into account also the continuity of work in each machine. Simultaneously with the making of the control board tickets a job card is made for the shop foreman's office board. This board contains a compartment for each man, and the cards are arranged to correspond with the master control board with the "next job" card always in front. As each man nears completion of the work in hand his gang boss goes to the board and takes the "next job" ticket, and gets the material and the necessary tooling equipment to the machine. The card stays with the work and then goes to the inspector, who, after inspection, passes it to the cost department. This system plans the work in detail for the foreman. It shows when machines are overloaded, when they are idle due to breakdown, man absent or out of work, all points of vital interest where costs and delivery are of prime importance.

There is one fundamental principle underlying all these

Fig. 6. Shop Control Board for Laying Out Machine Work in Advance

methods. In every case a standard or task is set as the object to be attained and that standard is set at the beginning of the job. All the methods provide a means of knowing whether or not the standard is maintained at all points in the progress of operation up to the completion of each particular task.

Each example given has been preceded by a statement as to the object to be attained. This is very important because the multiplicity of details which have to be dealt with will

often lead one off the track unless the purpose is kept steadfastly in mind.

It should be noted that while all this looks like so much clerical and accounting work, the viewpoint is not that of an accountant, nor could it be handled by an accountant; it is distinctly a management engineering proposition for an engineer.

The principles outlined have been adopted by the management of the Canadian Pacific in the creation of a special department, called the production department, attached to the chief executive of Angus shops. It is distinctly a new department for railroad shops and credit must be given to W. H. Winterrowd, chief mechanical engineer, for recognizing that there was no logical reason why methods of successful business institutions should not be incorporated into railroad shops. To the best of the author's knowledge, the Angus shops are the only railroad shops on the continent that have such a department, operating as a separate department with the full confidence and co-operation of the supervising staff, all working for one result. All foremen, general foremen, and other supervisors realize that one department, acting as a sort of clearing house for all material, can render better service than was possible when they each had to chase their own material from shop to shop. They also recognize that when a certain output is required, the special department can advise what operations are to be done each day, can advise on all items, and state what must be done daily so that the final result meets the requirements, because it has more complete information than any one department could possibly have or get. In all cases the basic schedules are developed by or with the departmental head concerned so that he feels that it is his schedule and consequently he realizes that he is being actively assisted by the management.

Discussion

The discussion of the paper brought out the fact that the scheduling system requires a very small staff to operate, as in a shop employing about 2,500 men, not more than four or five additional men are required to take care of the work created by the system, while a 50 per cent increase should be obtained in the output of the shop without increasing the supervision. The question as to the effect upon the scheduling system should piecework be discontinued was answered by Mr. Spidy, who said that the schedule system in itself is entirely independent of the piecework system. Should piecework be discontinued the check on individual operation obtained by the piecework foremen would be discontinued, but there would still be the check in every department which is made by the production staff in each shop. The discontinuance of piecework would probably result in some of the piecework staff being absorbed into the supervision, thus providing extra foremen to check up the work and see that it is performed. Mr. Spidy stated it as his opinion that a shop without piecework requires a production schedule that is more extensive than one operating with piecework, because of the loss of the check on the work of the individual which is obtained with the piecework system. The distinction between the schedule system and the piecework system is that the former cuts the time between jobs while piecework concentrates on the job itself.

J. Burns, works manager, Angus shops, C. P. R., emphasized the necessity for a schedule system in a large shop especially where equipment is being built and large quantities of material must be secured and routed through the shop in proper sequence. He also emphasized the importance of the scheduling system where the same shops are manufacturing parts for use on locomotives and cars in the erecting shop as well as on shop orders for outside points. The schedule determines the proper preference to be given the different classes of work so that in neither case will delay result through failure to meet conflicting requirements.

TRAM FOR DRIVING WHEEL TIRES

BY H. L. LINGO

The form of tram shown in the illustration is a great convenience for sizing driving wheel tires either in the lathe or on the boring mill, as the straight prong on the fixed head gives the exact size to turn the flange when the tram is set to the tread size. There is no chance of error, and either not having quite enough stock to make a proper flange or having to reduce stock with the throat of the flange former, which is a difficult job. The practice of finishing the tread of the tire to size, then drawing the tool back the required distance and cutting off the top of the flange, after which the flange is formed, is still in use in many shops. This can be changed and, on a boring mill with two tools

Construction of the Tram for Driving Wheel Tires

working at the same time, where it is known just what the height of the finished flange will be, it can be roughed out and finished with one head, while the other is roughing down the tread.

The wedge block which holds the movable head in place is nothing new, except in its application to the wheel tram, where it replaces the familiar set screw which usually was not even provided with a shoe to keep it from denting the pipe, and after it was in use for a while required all the tools most of the railroad machinists use at present—hammers and monkey wrench—to operate.

DISK AND BALL BEARINGS.—Exhaustive tests of disk bearings and ball bearings in railway service are being carried out in Sweden. Disk bearings have been used in one of the trucks of a passenger car which has made over 31,000 miles. The car weighs 36 tons, the weight on each journal being four and a half tons. A new type of ball bearing has been developed for railway service and in the laboratory of the manufacturers, bearings of this type have withstood a pressure of 20 tons during a number of revolutions, corresponding to more than 30,000 miles.

ETHYLENE FOR CUTTING AND WELDING.—According to the Scientific American, comparative tests have shown that ethylene is a good substitute for acetylene in cutting and welding operations. As far as heat of combustion is concerned, ethylene has a slightly higher co-efficient. Moreover, in the working of copper it has been found impossible to make a satisfactory weld with acetylene, because of the formation of carbon and the consequent blistering in the weld. This is not the case with ethylene. In addition to its availability for welding copper, the ethylene process of aluminum welding and lead burning makes for much better results than does the use of acetylene. Finally, ethylene has been found to possess considerable value for heating and lighting and is, therefore, a general purpose gas.

J. D. BLOUNT TRIES A NOVEL EXPERIMENT

The S. M. P. Knew that Tom Brown Was a Good Man but Also that Ashville Needed Waking Up

BY A. N. BUCKLEY

WHEN T. B. Shoan entered the Old Man's office he knew instinctively something was in the wind. J. D. Blount, the superintendent of motive power of the Buffalo & North Eastern, sat at his desk gazing out of the window wrapped in thought, oblivious to Shoan's customary "Good morning." T. B. Shoan busied himself arranging the morning's correspondence for Mr. Blount's perusal, picked the papers from the outgoing basket and attended to other routine matters, knowing from experience that "J. D." would speak his mind in due time.

As he turned to leave, J. D. spoke. "Shoan, have you noticed how the B. & N. E. has been increasing its maintenance of equipment expenses, especially in repair costs, at Ashville shops? Ashville has one of our best shop superintendents, Tom Brown, but something has gone wrong lately. Output has fallen and costs have gone way up. The power to be maintained at Ashville has not changed, our shop facili-

"Arrange for Brown to Spend a Week at the D. & O. Shops"

ties are the same, and while the increased labor costs would cover part of it, the combination of decreased output and increased costs demands a different explanation. Only two things can account for the condition—lack of proper organization and insufficient attention to improved methods and practices.

"Organization," continued J. D., "is absolutely essential to effective working of every plant. Proper organization means more than smooth co-ordinated efforts between foremen and the shop superintendent. It requires developed and trained responsibility and the fitting of understudies for everybody, from the shop superintendent to the errand boy. No man is big enough for his job who is afraid to train some one to take his place. The real executive is not necessarily the man who knows the most, but the man who can command the services of and direct the efforts of men more capable than himself.

"Efficient operation requires the continued study of better shop practices, intensive utilization of facilities and the elimination of all possible lost motion. Effective watching of

operation demands the assistance of records which will serve as the control factors of the shop superintendent.

"So to test my belief as to the underlying causes of Ashville's conditions, I have in mind a novel experiment. Arrange to have Tom Brown leave Wednesday evening to spend a week at the Mountain Dare shops of the D. & O., another week at the Johnston shops of the R. & P., and a third week at the West Brook shops of the N. T. C. That gives him less than 36 hours to get away, and unless he has a developed organization it will not enable him to completely plan operations during his absence. Then tell him on his return to report the results of his observations as applicable to Ashville's shop improvement."

When Tom Brown received the Old Man's instructions he was dumbfounded. Things were as Blount had suspected. Brown had a one-man organization—and Brown was that one man. Bill Scott, his general foreman, had often tried to assume part of the load of management, but Brown, one of the old school, ever jealous of his prerogative, had resisted all of these overtures. Consequently he was at a loss just what to do, realizing that the time at his disposal was insufficient to instruct his organization for the next three weeks' operation. However, he knew J. D. B. well enough to know that nothing short of implicit following of orders would suffice, so he decided to trust to luck and Bill Scott.

Results during the first week of Brown's absence were such as were to be expected. Bill Scott worked hard, but the task of assuming both Brown's duties and his own served as a heavy handicap. No understudies were available, so that he was unable to have a temporary general foreman. Visitors were slighted, correspondence attended to evenings, reports checked and certified at the expense of sleep in order that shop operation might be pushed during working hours, a task not altogether successfully accomplished, as the first week showed a slump in output.

Arriving one morning long before seven, he heard that the Old Man had come in on No. 4 during the night and was already somewhere on the premises. Apprehensive of trouble, he hunted up the Old Man and found him wandering through the boiler shop.

After a cheery exchange of greetings, the Old Man said: "Scott, it is as I expected. Brown hasn't a thorough organization here, and while I know you have worked hard it is too great an obstacle to overcome. But while Brown is observing how the other fellow gets results, we will inaugurate the beginning of a new era in the Ashville organization ready for his return. Call a staff meeting after work this afternoon."

Promptly at four o'clock the foremen gathered in the shop superintendent's office, where the Old Man told them the essentials of organization and the need for understudies. He then told each to select a competent understudy by morning, and he and Scott would complete a temporary reorganization which would be effective until Brown's return. And further, to insure the proper training of understudies, he stated that thereafter each understudy would be required to assume the duties of the man for whom he was to substitute three days each month.

That evening Blount and Scott provided for the morrow, arranging to have Jack Green, machine shop foreman, assume the general foreman's duties; George White, fitting

shop foreman, to take Jack's place, and so on, filling every position with a foreman or a mechanic for understudying. Of course, this did not have an immediate magical effect on restoring shop efficiency, but improved operation was steadily noticeable.

In the meantime Brown at Mountain Dare was beginning to realize the Old Man's motive in sending him away. The Mountain Dare shops were of about the same size as his own and similarly equipped, yet the average output was three to five engines a month greater than at Ashville and the costs lower. Surprised as well that Welsh, the D. & O. shop superintendent, should have so much time to spend with him, he learned that Welsh believed firmly in organization and direction of shop operation with control charts.

Brown learned that instead of blindly hunting for obstacles, Welsh spent hours at his desk carefully studying results from these records, planning his campaigns for im-

He Was Surprised that Welsh Had So Much Time to Spend With Him

provement from their indications and depending upon the ability and training of his organization to accomplish results.

The days passed swiftly for Brown, and he eagerly went into erecting shop, boiler shop, blacksmith shop and machine shop practices and operations. Unhampered by details of shop operation, free to investigate in any direction, and alert with the new-found consciousness of the rut in which he and Ashville had been traveling, he found the days far too short. Aroused by the developing realization of possibilities for improvement at Ashville, he observed, studied, asked questions during the day, and in the evening, when not joined at the hotel by the shop superintendent or some foreman, spent hours planning applications in his own shop of what he found the other fellow doing.

Time slipped by and Brown returned to Ashville, keener from contact with other minds, more dissatisfied with results than before, but fortified by his observations, with valuable suggestions for improvement.

Entering his office the morning of his return, he found the Old Man waiting for him, with his chief clerk. The Old Man greeted him cordially and said, "Tom, I was so anxious to learn of your visit that I decided to run up and talk with you instead of waiting for your written report. But first I want to tell you of the temporary organization we have effected."

"That's right," said Brown after listening to the Old Man,

"and that organization will stand. And I am further convinced that when I or the general foreman notice a workman using a wrong practice or doing something that appears wrong we should hunt up the foreman instead of correcting the man. Then if the foreman is wrongly informed he can be set right, without the man learning of his ignorance. At the same time it prevents misunderstandings and needless interference when some deviation from usual practice is required. A shop spirit is built up, increased respect of the workman for his foreman insured, and responsibility absolutely fixed on each man, all of which results in bettering output.

"But I found out that organization not only helps to keep things running smoothly, but it will give me an opportunity to control things if I have the proper records. I am going to have started immediately control charts showing monthly comparisons of man-hours per locomotive repaired and man-hours per 1,000-lb. tractive effort. In addition, in order that I can properly read these figures, I am also going to add a sheet showing the number of heavy operations each month, as for instance, new driving boxes, new cylinders applied, side sheets, fireboxes, flues repaired, etc., and the number of man-hours for the standard unit, so that the approximate effect in man-hours on the month's output by these operations can be readily figured. Then, instead of blindly hunting through the shop for obstacles and points for improvement, I can effectively plan and direct operations from an accurate knowledge of what is going on."

The Old Man was intensely interested to see how Brown had grasped the situation during his three weeks' absence and placed his finger on one of the vital needs for the betterment of Ashville's operation. In fact, he had not only appreciated Blount's view on organization, but he had already

We Can Use Our Gap Grinder for Crank Pins

indicated how he was going to make the organization work for and serve him.

Continuing, Brown said: "You remember whenever you tried to get me to install a scheduling system I always replied that I could keep things lined up, and by weekly meetings with the foremen, together with daily contact, we could accomplish all that a schedule system would, and that we didn't need any of these paper systems to run Ashville.

"Well, from now on Ashville is going to have a schedule system. Why, I'd as soon run a ship without a rudder as this shop without a schedule system. The control charts will give me a general hold on the shop, but the schedule system will give me the touch with details that I need. It will show me the weak spots and the delays, so that I can employ my time just where it is needed. It is the man that is falling down, it is the overloaded department that I am concerned with, not the man that is up-to-date. And my daily delay sheet will give me just this information. Then I can investigate the cause and apply the remedy.

"Then another of my stock arguments was that quality of output would be slighted to meet the schedule, big jobs discovered after an engine was shopped would be patched instead of the part renewed if it would result in a fall-down on schedule. The answer to that is a boiler and machinery inspector reporting directly to me and not responsible even to the general foreman. These inspectors will go over the engine not only before it is shopped, but while it is undergoing repairs. Being responsible solely for inspection and familiar with inspection limits, they should be consulted by a foreman before a new part is ordered, instead of repairing the old part. By holding them responsible for quality of output and in no way for quantity, quality will be maintained and where necessary the schedule corrected if something unexpected is found.

"And we're not going to stop with starting an organization, but we're going to wake up in the use of our shop facilities. Aside from some rearrangements required to give better shop movement for material, our big drive is going to be in getting all we can from our machines by using them for what they are best suited, by getting all we can in speed and feed and by using jigs and fixtures.

"The first place we are going to start is with our gap grinder. This is used only for grinding piston rods and valve

stems and stands idle over half the time. While larger than needed, we can use it to grind the bearing on all our crank pins, reducing the overtime on our crank pin lathe, due to inability to rough and finish all the pins required. We can also use it, with ample steady rests, for truing up worn air pump piston rods, and if we still have time available, will consider grinding journals of new driving axles. In fact, Ashville expects to begin giving results."

Brown was so deeply interested that more than two hours elapsed while he recited what he had seen and what he expected to accomplish. J. D. Blount listened intently, interrupting only occasionally to ask a question or grunt an assent. As Brown concluded he turned to him and said, "Tom, what I told Shoon was right. It was only organization and methods that were wrong with Ashville. The personnel is here, but it has lacked direction. And you have proved to me that to keep alive we must get in touch with the other fellow."

Then, turning to Shoon, he continued: "Shoon, we will require, as a test of organization and the ability of the executive to put himself into the organization as well as furnishing an opportunity of getting out of a shop rut, that each shop superintendent of the B. & N. E. take two or three weeks each year visiting other shops. Arrange to have Davis of Corning follow Brown's route next week."

THE NATIONAL AGREEMENT WITH THE SHOPMEN*

Securing Co-operation from the Workmen; Apprentices; Stabilizing Working Conditions

BY FRANK McMANAMY

Manager, Department of Equipment, Division of Liquidation Claims, U. S. Railroad Administration

THE two real difficulties in connection with private operation of railroads immediately prior to the time the railroads were taken over by the government were labor conditions and financial conditions which I have stated I believe in the order of their importance; because the government could at any time relieve the financial conditions, but it could not so readily relieve the labor conditions; and after all railroads or any other industry are operated by men.

It is simply restating an acknowledged fact to say that the labor situation was extremely serious in the latter part of 1917, due to a number of causes. Large numbers of men had been drawn from the railroads for military purposes, making a serious shortage of skilled men in the railroad business. Because of the failure of the railroads themselves during a long period of years to take necessary steps to train mechanics by maintaining a full quota of apprentices, there was no available source of supply and no large number of apprentices which could in an emergency be drawn on to do mechanics' work. There was also a widespread distrust on the part of railroad labor of the motives behind any attempt to increase working hours or in any other way to modify the working agreements which had been obtained by railroad employees after years of negotiation and the expenditure of vast sums of money, as well as by numerous strikes which were disastrous alike to employer and employees. The organizations looked with a suspicion on any request to waive any of the privileges thus gained and feared that the national emergency would be taken advantage of to take away from them some of the privileges which they enjoyed as a result of the efforts of their organizations.

There was no supply of men to draw from to meet this emergency and the situation could only be met by co-operat-

ing with labor in a fair and open manner and by obtaining their consent to the temporary waiving of some of the provisions of their agreements. They could never have been accomplished by individual carriers, because there could be no assurance given which would be satisfactory to the employees that once these privileges were given up they would ever be restored. Therefore, it appears to be conclusive that at this period no other agency except the United States Government could have effectually handled the labor situation as it existed at that time.

The first national agreement covering all railroad shopmen is represented by Director General McAdoo's letter of February 14, 1918, to A. O. Wharton, president of the Railway Employees' Department of the American Federation of Labor, in which an understanding with shopmen was reached whereby certain privileges long enjoyed by them and covered by many agreements with railroads were temporarily waived on the assurance of the Railroad Administration that the agreements in full would be restored and observed as soon as the condition of locomotives and cars would justify it; and it is but fair to the representatives of the shopmen to state that when this matter was presented to them an understanding was promptly reached by which they waived privileges obtained through years of negotiation, on the assurance of the Railroad Administration that their agreements would be protected; and that letter constituted the working basis between the Railroad Administration and the shop employees from the day it was issued up to the date of the signing of the national agreement; and from that moment that letter became effective and the working conditions were regulated in accordance therewith, a constant improvement in the condition of motive power and cars became apparent.

Many changes have been brought about by the war, none of which are more far-reaching or important than the changes

*Part of an address before the Western Railway Club, Chicago, March 15, 1920.

in the condition of and the method of dealing with labor, and in my opinion the employer in the future who expects harmony, efficiency and co-operation from his employees must devote at least as much thought to the selection, training and treatment of his employees as he gives to the erection of his shops or factories and the installation of the equipment. In other words, if we are to have a complete, smooth-working, efficient machine, which includes employees as well as machinery, as much time and thought must be given to the study of what might be termed "humanics" in connection with the treatment of employees as we give to the study of mechanics in connection with the erection or operation of the plant.

Suggestions by Workmen

It is a recognized fact that in practically every human activity increased opportunity for a common understanding has been productive of favorable results; therefore, it is difficult to understand just why the average railroad shops is behind industrial establishments in the matter of having a method for obtaining from their employees co-operation and advice relating to shop methods and conditions.

The director general observed and recognized the advantages to be derived from having sympathetic understanding and co-operation between the employees and the officials, and tried to work out and have put in effect a system which would insure a greater degree of co-operation and give to the management the full benefit of the knowledge and experience of the workmen and their suggestions as to improvements in methods to bring about increased efficiency. Several months ago he suggested to the regional directors the advisability of arranging for employees through their regular organizations to select a committee for the purpose of considering with the local officials questions affecting matters relating to shop operation and output.

The plan under which this suggestion was to be carried out was by regular meetings between the local officials and the committee selected from the shopmen to discuss with the utmost frankness all questions involving the planning and the carrying on of the work, inviting suggestions from the committee and endeavoring to give full weight to all of these suggestions that might be meritorious. It, of course, must be clearly understood that these meetings were not to be for the purpose of adjusting grievances, either directly or indirectly, and that such matters must not even be discussed. The following illustrations were given of subjects which were considered as probably suitable for such discussions:

1. Co-operation between departments.
2. Proper storage and care of material.
3. Distribution of material.
4. Tool equipment and distribution of hand tools.
5. Grouping of machine tools.
6. Machine operation and crane service.
7. Scheduling work through shops.
8. Better classification of freight car repairs and whether certain work can be more economically done.
9. Improved methods of making repairs.
10. Method of handling and disposition of scrap.
11. Inspection of scrap and reclamation of usable material.
12. Condition of shops and shop grounds.

The above was not given as a complete list of the subjects which might properly be discussed, but simply as a general outline of matters on which a discussion would no doubt prove beneficial. The plan contemplated one representative from each of the crafts, except in the larger shops where the representation could be increased as might be found desirable. The ranking mechanical department official at the shop in question should preside, all others attending the meeting to be on exactly the same basis so far as the discussion of the matters presented was concerned. In order to have a free discussion it would, of course, be necessary to have the representatives of the employees and the junior officials ex-

press their opinions first. Otherwise a free discussion would not be possible, because in some instances men might hesitate to express opinions contrary to those of the ranking officials.

Owing to lack of time this plan was never put into complete operation, but was submitted to the federal managers, and many expressions of approval were received. Similar plans are now in operation in many industrial establishments and have proven to be very beneficial.

Advantages of National Agreement

National agreements cannot be made in all lines of industry, but the transportation industry is essentially a national one. The work of conducting it is substantially the same in Maine and California, in Montana and Texas.

Equipment to a large extent has been standardized, partly by the different associations of railroad officials, partly by law, and partly by the Railroad Administration. Standard transportation rules have been adopted by practically every railroad in the country. The interchange of freight cars is complete. Tickets and bills of lading are practically uniform; and with the consolidation of ticket offices throughout the country, which was adopted by the Railroad Administration, the practices in this respect became almost as nearly standard as in United States post offices. Under such conditions it is not only idle but illogical to think of keeping the man-power which operates the railroads separate and working for different rates of pay on different railroads and under different working conditions.

Among the principal benefits to be derived from the national agreement is the stabilization of shop organizations and the elimination of what had become almost an institution in connection with railroad shop labor; that is, the "boomer" mechanic, who was continually moving from place to place in search of conditions more to his liking. Everyone will admit that the ideal shop organization is a force of what has by the boomer been termed "home guards," who select railroad work shop as their permanent occupation and who wish to establish themselves permanently at the point where they are employed, own their homes, take a part in the general affairs of the community, cultivate a circle of friends, educate their children, and in general enjoy the privileges and exercise the duties which are supposed to fall to the lot of the average American citizen. Under such conditions men become familiar with the work required of them, study the details of the particular equipment which they are required to handle and the peculiar conditions which they are required to meet, take an interest in the general operation of the railroad, and become a part of the permanent organization which is necessary for the successful operation of any property.

A national agreement insuring equal privileges to men at all points on all lines will help to bring about this desirable condition. On the other hand, if we are to have on one railroad certain favorable conditions of employment which do not exist on other railroads it will necessarily cause men on a large number of railroads to be dissatisfied with their working conditions and to constantly, and we may as well say properly, strive for an improvement of their own conditions to compare with those on the neighboring line. This affects efficiency in many ways. It not only results in a constantly changing force of mechanics, which is hurtful, but it is also fatal to that spirit of loyalty to the employer's interest without which no railroad can be efficiently operated.

A national agreement with railroad shopmen brings stability to the railroad organization, and by virtue of the large number of men covered by it acts as an insurance against local disputes in the same way that life insurance or fire insurance protects the individual by distributing the losses over a large number of those participating in it.

It is entirely possible for the individual at a local point to become so dissatisfied with certain working conditions, which are in no way general and which can be readily remedied by a reasonable application of the agreement, that they will go

on strike to remedy conditions which could be much better handled in another way. As a matter of fact, however, such local strikes are not desired by the organizations of the employees any more than they are by the railroads, and while we have, during the period of federal control, had more than 200 of such local strikes, not a single one of them has been sanctioned by the national organizations, and these organizations have always been helpful in restoring normal conditions.

The Apprenticeship Question

One of the conditions which we developed as a result of the national agreement is illustrative of the fact that the arguments which are used by one side or the other to any controversy are often based on the wildest kind of a guess, for the reason that no one has ever developed the facts. I refer to the apprenticeship rules in the national agreement. The employees have for years favored regulating the number of mechanics by regulating the number of apprentices, with the purpose in mind of avoiding an over-supply of mechanics with its resultant effect upon the rates of pay. The employers have opposed this plan of the employees because they believed it was unfairly restricting the number of mechanics which were being trained and was reducing the supply of mechanics to an extent which made successful shop operation difficult.

The ratio which had been agreed to by the employees and the officials on many railroads of five to one was held by the employers to be too low, and it was urged that this ratio would not provide a sufficient supply of mechanics. In negotiating the national agreement we felt justified in accepting the fact that such agreements were satisfactorily meeting conditions on a large percentage of the railroads of the country as evidence that the ratio was reasonable; therefore, the ratio of one apprentice to five mechanics was incorporated in the national agreement.

In order to bring out as nearly as possible just what this would mean, I immediately started in to develop the actual conditions which existed and to see how nearly we were in fact working to the ratio which was set forth as the proper one. A complete check of all the railroads in federal operation showed that we had in service 17,268 apprentices, while under the ratio provided in the national agreement we were entitled to 64,182.

In the Eastern region the ratio of mechanics to apprentices was 21.40; in the Allegheny region, 30.95; in the Pocahontas region, 14.18; in the Southern region, 13.48; in the Central Western region, 12.75; in the Northwestern, 22.44; and in the Southwestern, 11.89, making an average for the country of 18.58 mechanics for each apprentice.

It will thus be seen that the opposition to this rule was due almost entirely to the absence of complete and accurate information concerning existing conditions. We were informed by many railroads that the reason the number of apprentices was so extremely small was because they were unable to obtain more. If that is true it would certainly seem to be illogical to dispute with the employees over the proper ratio and to blame the shortage of mechanics on the restrictions contained in the working agreements. Our investigations, I think, show without doubt that the ratio of apprentices provided for in the national agreement is reasonable and fair, and that it will provide a sufficient number of skilled mechanics if it is consistently followed.

Based on Former Agreements

There is nothing freakish about the present national agreement with shopmen, and it was not, as some have assumed, adopted without the most careful and thorough discussion and consideration. It is based on the agreements which were in effect on a large percentage of the railroads of the country and which had proved to be practicable and workable. It was discussed for approximately four months by a joint committee representing the different regional directors and a

committee representing the various national or international shopmen's organizations. The rules which were agreed to at these conferences and those on which no agreement could be reached were then referred to the Board of Railroad Wages and Working Conditions, where both sides presented arguments, and the matter was in the hands of this board for approximately four months. The wage board failing to agree upon the terms of the national agreement, it was then turned over to the mechanical department of the Division of Operation, where, with the assistance of the Division of Labor, the agreement in its present form was negotiated and submitted to the director general, who approved it on September 20, to become effective October 20, 1919.

It is true this agreement does not cover every difference of opinion which may arise between local officials and local committees or between general officials and general committees, and it was not expected to. It does, however, provide a sound basis upon which to handle such differences if it is accepted by both sides with a sympathetic purpose to carry out the very obvious intent of the different rules.

It is true that we have received in the neighborhood of 2,500 requests for information concerning the application of the various rules, which has practically all been furnished. Some of the questions presented are of a character which cannot possibly be covered by any national agreement or by any interpretation of an agreement, but are local matters which can only be handled with a knowledge of local conditions.

Rules 35 and 36 are worthy of special mention because they provide means for settling all grievances which may arise. Rule 36 also contains the following provision for avoiding strikes which were never before contained in a working agreement: "Prior to the assertion of grievances as herein provided, and while questions of grievances are pending, there will neither be a shut down by the employer nor a suspension of work by the employee."

It is not to be expected that this provision will entirely prevent either of the evils it is aimed at any more than the command, "Thou shalt not steal," has made all men honest, but it points the way to a better method of handling disputes and provides a working basis on which to adjust them.

The special rules of each craft which set forth the qualifications of mechanics will provide a better organization than the plan of training specialists who can do but one thing, which perhaps through necessity was followed in many shops, as it is generally admitted that the supply of all-around mechanics was invariably less than the demand.

The agreement properly applied will stabilize working conditions, remove causes for disputes and provide means for settling them, enable you to build up permanent forces, and provide through the apprenticeship system for an adequate supply of mechanics to successfully and efficiently operate railroad shops, and this is all it was intended to do.

Discussion

The discussion of Mr. McManamy's address was something of a disappointment, considering the large attendance at the meeting. Summed up, there seemed to be a feeling that the men were working at a low rate of efficiency and that there was not the incentive that there should be to encourage them to put forth their best efforts. An instance was cited where the man-hours per engine for general repairs had increased from an average of about 6,200 in 1917 to 8,000 in 1919.

Several speakers commented on the difficulties caused by the classification of men of little or no training or ability as full mechanics. All-around mechanics must be developed.

Stabilizing the working conditions should do much to prevent the shifting of men from one road to another, although this has thus far not been entirely eliminated.

The routing or schedule system has helped to offset the loss in efficiency caused by the cutting out of piecework.

The roads generally are not doing what they should in connection with the training of apprentices.

THE METHODS USED IN HEAT TREATING STEEL*

Concise Statement of Salient Points, the Knowledge of Which is Essential for Correct Practice

THE modern practice of the heat treatment of steel has become so complex, involving as it does a very definite knowledge of the thermal changes occurring in the metal as it is heated or cooled, *i. e.*, the critical transformations, the initial microstructure of the metal and the structural changes which may be effected by various treatments, correct methods of heating and cooling, the modifications of practice induced by the introduction of various alloying elements, etc., that even an elementary discussion of the subject becomes involved and complex. Below are listed a few of the salient points in the various fields of the heat treatment of steel, a thorough knowledge of which is absolutely essential for the proper handling of material in these operations.

Steel is essentially an alloy of iron and carbon, disregarding for the moment alloys which are added to impart certain properties. The carbon is present as a definite compound with a certain amount of the iron, *i. e.*, Fe_3C , called cementite; it is the condition of this cementite which governs the physical properties of the steel.

In the stable state, at ordinary temperatures, this cementite is separated (precipitated) from the ferrite, as the iron is called, and can be recognized under the microscope as a separate structural constituent.

If the steel is heated, the carbide passes into solution in a certain amount of the iron at a temperature of about 725 deg. Cent. (1327 deg. F.) represented by the line *PK* in the diagram. As the temperature is raised, this solution gradually absorbs the remaining ferrite, until the respective temperature or the line *GOS* is reached, depending on the carbon content, when the whole will be a single solid solution.¹ Steel in such condition preserved down to room temperature would show but one constituent under the microscope. The solid solution which is preserved by very rapid cooling, is much harder at room temperature than the separated condition, which is readily obtained by annealing. Intermediate states are obtained by varying the speed of cooling from the high temperatures and also by slight re-heating of a rapidly cooled specimen. The temperature at which the carbide passes into solution may be detected with a pyrometer, because of the absorption of heat when the change takes place. The temperature range in which this change takes place is called the critical range of the steel.

The physical properties of the steel can often be judged from the "grain," which in works' practice is seen in the fracture, and in the laboratory may be seen in the microstructure. In general, coarse grain is taken to indicate weakness and brittleness, while fine grain would indicate strength and toughness. Coarse grain is produced by long heating at high temperatures, and by passing through the critical range slowly in cooling. Fine grain is found in samples heated to but slightly above the critical range and cooled more or less rapidly. Very coarse grain may be reduced by forging, and by cold work followed by annealing.

Any of the various heat treatments applied to a steel may be reduced to a combination of the following elements:

(1) heating at a definite temperature for a definite length of time; (2) cooling from this temperature at some desired rate, and (3) re-heating if desired. The more complex treatments consist in the duplication of one or more of these elements together with changes in the various temperatures, rates of cooling, etc. These elements will be considered under the designations—Annealing, Hardening and Tempering.

Annealing

The purpose of annealing steel is: (1) to soften it for machining; (2) to give certain physical properties, *e. g.*, to soften it for some definite service or make it stronger and less brittle by refining the grain, and (3) to remove stresses due to cold-working, quenching, etc.

Temperature—For the purpose of softening or refining the temperatures chosen are usually the same and may be found in the shaded area of the diagram. It will be seen that they vary with the carbon content of the steel; they are further modified, sometimes to a marked degree, by alloys present. For softening in machining it is not absolutely necessary to heat above the critical range.

For removing stresses there is in the case of cold-worked

material a fairly definite temperature at which the effects of cold work are removed. This usually lies between 500 deg. and 575 deg. C (932 deg. and 1067 deg. F.); that is, somewhere in that range re-crystallization takes place and the

elongated grains divide and become equi-axed. Re-heating after quenching will be considered under Tempering.

Rate of Heating—The size and the shape of the piece must be considered, it being especially important in large and irregular pieces not to force the heating, as the outside of the article and thin parts would be greatly overheated. Pieces should be arranged in the furnace to insure as even heating as possible, and in gas furnaces should be set on supports to allow free passage of the gases underneath the piece.

Rate of Cooling—This is determined, in the case of annealing above the critical range, by the properties desired, by the size of the piece and by the carbon content. For maximum softness the piece is allowed to cool in the furnace. Very large pieces may be removed from the furnace and cooled in the air, their size preventing too rapid cooling. On the other hand, thin pieces of high carbon content cool rapidly enough in air to become quite hard.

"Normalizing" may be considered under the head of annealing. It consists in heating the steel above the critical range and cooling in air and serves to put the steel in an unstressed condition of good crystal size and arrangement. It also minimizes the danger of quenching cracks in high-carbon steels, especially on repeated hardening.

Double Annealing—This is done for the purpose of maximum grain refining. It consists of heating to a temperature somewhat above the critical range, then air cooling or quenching, followed by reheating to a temperature just below the critical range.

Divorce Annealing—Annealing to spheroidize the cementite. Long heating at just below the critical temperature converts the carbide from plate form to granular form; it makes steel especially tough.

Protection During Heating—This may be effected by using neutral or reducing ("hazy") flames when burning gas or

The great importance of correct methods in heat treating modern steels including alloy and high speed steels makes this article a timely one.

*From Letter Circular VIII-2, compiled and issued by the Bureau of Standards, Department of Commerce, Washington, D. C.

¹This discussion refers to steels of less than 0.9 per cent carbon. Above that percentage, the excess constituent is cementite instead of ferrite. Hence the range *PS* to *GS* represents absorption of ferrite; the range *SK* to *SE* represents absorption of cementite. At 0.9 per cent all the dissolving occurs at once.

oil, by heating in lime or carbon, and by the use of annealing boxes.

Overheating—Too high annealing temperature; too long heating (size of piece must be considered). "Burning" of steel results from heating to the region of incipient fusion. Overheated steel can be restored by suitable heat treatment, especially in connection with forging. Burnt steel cannot be restored.

Hardening

Temperature—The temperature must be above the critical range; the piece should be heated long enough to insure complete solution (special precautions for alloy steels); too high temperature must be avoided. The annealing range shown in the diagram may be taken as a guide for quenching temperatures. The higher the carbon, the greater the precautions

Diagram Showing Critical Temperature Ranges for Steels of Various Carbon Content

to keep the quenching temperature but little above the critical range. In steels having more than one per cent carbon, normalizing from above the upper critical range (line SE) may precede quenching, if excess carbide is in plate form which would weaken the steel.

Method of Heating—This may be: (1) Open furnace; precautions same as in annealing; or (2) baths of molten lead, barium chloride, sodium chloride, etc. The latter has the advantage of accurate temperature control, uniform heating, no danger of overheating. Salt baths give clean steel on quenching, but decarburize the surface with long heating.

Quenching—Different liquids have different speeds of cooling and so impart different degrees of hardness to steel on quenching. The following represents an average of the data from many different sources, and indicates roughly the relative hardening that may be expected:

Quenching medium	Time of cooling specimen from 800 deg. C. to 250 deg. C. (1472 deg. F. to 482 deg. F.)
Water at 20 deg. C. (68 deg. F.)	1.0
Water at 50 deg. C. (122 deg. F.)	1.2
Water at 80 deg. C. (176 deg. F.)	1.4
Water at 100 deg. C. (212 deg. F.)	3.0
Brine at 20 deg. C. (68 deg. F.)	1.0
Brine at 60 deg. C. (140 deg. F.)	1.0
Brine at 80 deg. C. (176 deg. F.)	1.2
Alcohol 20 deg. C. (68 deg. F.)	1.0
Corn oil 20-75 deg. C. (68-167 deg. F.)	1.3
Fish oil	1.5 to 1.9
Lard oil	1.6 to 1.8
Sperm oil	1.7
Linseed oil	1.8
Cottonseed oil	1.9
Mineral oils at 20 deg. C. (68 deg. F.)	1.3 to 2.5
Mercury at 20 deg. C. (68 deg. F.)	2.5
Glycerine at 20 deg. C. (68 deg. F.)	3.0
Air at 20 deg. C. (68 deg. F.)	15.

The quenching power of cooling baths decreases as the temperature rises, but oil changes very little. Salt solutions do not change as much as water. Cooling coils may be used for cooling the bath. The amount of quenching liquid should be sufficient in relation to the size of piece to prevent an

undue rise of temperature of the bath. Stirring the bath and moving the piece causes it to come in contact with cool liquid.

To prevent warping, thin pieces should be quenched axially, should not have excessive scale, and should be normalized after cold-working before quenching.

Tempering

Purpose—Tempering relieves stresses due to quenching, reduces brittleness, especially in water-quenched pieces, and toughens the steel. It produces elasticity for springs.

Temperatures—Tempering may be done at any temperature below the critical range, but usually between 100 deg. and 500 deg. C. (212 deg. and 932 deg. F.), depending on the use to which the material is to be put. The range for various purposes is as follows: 100 deg.-150 deg. C. (212-302 deg. F.), razors and other hard cutters (brittleness not objectionable); 200 deg.-300 deg. C. (392 deg.-572 deg. F.), cutting tools (chisels, milling cutters, knives, etc.); 300 deg.-400 deg. C. (572 deg.-752 deg. F.), springs (high elasticity); above 400 deg. C. (752 deg. F.), great toughness and resistance to shock.

Regulation of Tempering—Longer heating causes greater softening. Long heating at low temperatures is better than short heating at high temperatures; it gives greater uniformity. The rate of cooling has little influence on the results, as there is no transformation. Pieces are often quenched for convenience. The temper color is due to the formation of a thin surface layer of oxide, and is a true indication of the degree of softness at the surface when there is free access of air. Longer heating at the same temperature gives a darker color.

Tempering baths of oil, fused salts or fused metals offer the advantages of accurate temperature control and uniformity.

"Blazing off," i. e., heating to the flash point of the oil after oil quenching, is undesirable as it results in uneven heating with excessive heat at the surface. Large pieces may be tempered by removal from the quenching bath while they are still hot enough to temper of themselves, but exact regulation is difficult.

Case Hardening

The purpose of case hardening is generally to impart a very hard wearing surface with a softer and more resilient interior for withstanding shock, as in cams, gears, etc. The composition of the base steel is usually about 0.2 per cent carbon; some alloys are advantageous, especially a small amount of chromium.

Carburizing—The article is heated for a suitable length of time in solids or molten baths. Solids used for this purpose are mixtures of charcoal, charred leather, bone, etc., with barium carbonate or other carbonates. The time required is from five to 20 hours at 875 deg.-950 deg. C. (1607 deg.-1742 deg. F.). A deep case is produced.

Liquids used for carburizing are molten potassium cyanide, sometimes mixed with chlorides, other cyanides, etc. From one to 15 minutes at temperatures from 800 deg.-900 deg. C. (1472 deg.-1652 deg. F.) are required and a thin case is produced. These liquids are highly poisonous.

In "pack hardening" the pieces are heated just above critical range (750 deg. C. or 1382 deg. F.) while packed in solid cements, for about two hours, after which they are quenched in oil. This process is used only on high-carbon steels.

Portions of pieces to be left uncarburized may be protected by plating with copper, etc.

Heat Treatment—The aim is to produce a hard case, with an interior refined of the effects of overheating and rendered capable of resisting shock. After carburizing with solids, double quench the pieces, first from above the critical range of the core to refine the grain of the core after the long heat-

ing, and then from just above the critical range of the case, to harden the case properly.

When liquid carburizing agents are used the carburizing bath is usually kept at the hardening temperature and the piece quenched directly.

The pieces may be tempered as desired.

Alloy Steels

Though the heat treatment of such steels is, in principle, essentially like that of the plain carbon steels, the introduction of the alloying element, *i. e.*, nickel, chromium, tungsten, etc., modifies the practice so profoundly that each type requires a special study.

In general, the addition of the special element may modify the treatment and therefore the properties in the following ways:

(a)—By the lowering of the critical ranges or transformation temperatures, forms which in plain carbon steels are stable only at high temperatures may become the stable forms even upon slow cooling. Nickel is one illustration of this behavior.

(b)—The critical changes may be made to take place much more slowly than in carbon steels of the same carbon content so that the transformation temperature is raised upon heating and lowered upon cooling. Chromium illustrates this behavior. In general, the alloy steels are much slower in their response to heating than are the plain carbon steels, thereby permitting a longer heating period of a higher temperature without exposing the steel to the danger of becoming so coarse as would be the case if the special element were not present.

(c)—The structural condition in which the special element exists determines largely the properties of the steel and to a large extent the heat treatment necessary to develop the required properties, *i. e.*, whether the added element enters into the ferrite constituent (nickel is a case of this), or into combination with the carbon (as with chromium and tungsten). The double carbide formed in the latter cases increases the mineral hardness of the steel without increasing the brittleness to such a degree as an addition of an equivalent amount of carbon would do.

(d)—By the addition of two or more special elements, the advantages of each may be retained and the disadvantages largely neutralized, as in chromo-nickel steels which, as a type, probably represent the best all-around alloy steels in commercial use for general purposes.

Reference to some of the books on the subject of special steels must be had for definite information upon the special alloy steels, their heat treatment, characteristic properties, and special uses for which each is adapted. Most of the steel companies manufacturing special grades of steel have worked out, experimentally, the heat treatment necessary to bring out the most desirable physical properties of their particular steel; upon purchasing, directions are given concerning the heat treatment.

High Speed Steel

The introduction of large amounts of alloying elements in high speed steels caused radical changes in the nature of the steel. The heat treatment therefore differs greatly from that usually applied to steels. Hardening is effected in principle as before by bringing the carbides into solution in the iron and cooling at such a rate as will leave them in solution. The presence of large amounts of tungsten and chromium changes both the temperature required for affecting the solution and the allowable range of cooling rates.

Annealing—This is effected by heating at 850 deg. C.-900 deg. C. (1562 F.-1652 deg. F.) for periods sometimes as long as five hours, depending on the nature of the steel.

Hardening—The steel is heated very slowly to about 700 deg. C. (1292 deg. F.) then very rapidly to about 1200 deg.

C. (2192 deg. F.) and cooled in any way desired,—air, air-blast, oil or water. The rate of cooling has no great influence on the hardness, as the carbides remain in solution except on extremely slow cooling.

Tempering—High speed tools are generally not tempered, although tempering at 500 deg.-600 deg. C. (932 deg.-1112 deg. F.) is recommended for some tools. After water-quenching, it may be advisable to remove cooling stresses by tempering at a low temperature.

Special Alloys—Certain alloys, not properly steels, have come into use as high speed cutters. "Stellite," a cobalt-chromium-tungsten alloy, requires no heat treatment and responds to none. It is cast to shape and ground. Other unusual combinations of chromium, nickel, zirconium, molybdenum, etc., have been used, the nature of the alloy determining whether it requires heat treatment and in most cases such treatment is not required.

LOCOMOTIVE USED AS A SHELL PRESS.—The proceedings of the Societe des Ingenieurs Civils de France contain the account of an ingenious device for drawing down 75-mm. steel shells during the war. Like all other works in France, the Bordeaux shops of the South of France Railway Company were called upon at the outbreak of war to contribute material for the defense of the nation. In view of the urgent demand for larger quantities of 75-mm. shells they adapted a portion of their machinery to the making of these, starting from steel bars cut to length. These were upset hot in a die and the piece was then given a cup shape by means of a punch and die system. It was then necessary to draw down the piece to a cylindrical shape, requiring a pressure of from 80 to 100 tons, and for this the Bordeaux works of the Midi railway had no machine available. Considering the time it would have taken to build, or to await the delivery of a hydraulic press for the purpose, they looked around for temporary means of increasing the shell supply. A trial was made with a powerful locomotive built for service on heavy gradients, one of which happened to be lying idle pending repairs.

The locomotive was moved to a position in front of a stout wall on which the drawing room die holder was supported. It was then raised so that the wheels were clear of the rails and a punch was fitted to the tail rod of one of the pistons. A cup was then heated to a red heat and placed in the die, when the opening of the regulator valve drove the punch forward and caused the cup to pass through the die. The test being successful, it only remained necessary to make the installation more convenient for use. It was operated successfully for about two years and produced several hundred thousands of 75-mm. shells, pending the putting down of a more suitable hydraulic plant. It enabled the works, from the very commencement of the war, to do away with the manufacture of shells by boring out of the solid, thus saving a large quantity of metal and much time.—*Engineering, London.*

OPERATING METHODS AND FUEL ECONOMY.—If you would get out and get the slow orders off your railroad, and get trains made up so that every train doesn't have to stop and set out something at every cross road; if you would see that your despatchers know what is going on and make them take the responsibility which is justly chargeable to them, the engineers and firemen would be relieved of a big load that they have been carrying for years and your fuel bill and other operating expenses would be reduced more than can ever be accomplished by further education of the engine crew.—*H. C. Woodbridge at the Central Railway Club.*

GENERAL PURPOSE PLANER

While there has been little change in the general appearance and operation of planing machines for many years, several improvements have been embodied in the later models to make them more efficient and capable of higher production. Among the improvements embodied in the line of planers manufactured by the Cincinnati Planer Company, Cincinnati, Ohio, may be mentioned the use of herringbone

Cincinnati Planer Provided With Latest Improvements

gears in the first reduction of the table drive, forced lubrication, quick power traverse of the heads, and the box type bed. These improvements make the planers of particular interest to machine tool users.

The planer bed is designed for maximum rigidity and is of a box type construction, which not only prevents the accu-

mulation of chips, but also safeguards the operator against catching an arm or leg between the table and the usual open bed cross-ties. The walls of the bed are securely tied together by heavy T-shaped girths.

Forced feed lubrication is provided by means of an oil pump positively driven from the main drive shaft. The oil is thus circulated from a reservoir under pressure to both vees at a central point. It is then distributed outward to the return pockets at the ends of the bed, whence it is returned to the reservoir by means of suitable pipes. A special form of oil grooving provided on the table vees insures complete lubrication even when the planer is operating on short work.

The advantage of herringbone gears in the initial reduction of the table drive lies in the smoother motion imparted to the table. The use of herringbone gears, together with the rigid construction of the machine throughout, eliminates chatter and tool marks on the work. Perhaps the one feature which adds to the high production capacity of the planer more than anything else is the rapid traverse of the heads, operated by control levers conveniently located. Power traverse of the rail heads is provided on all sizes of Cincinnati planers from 30 in. to the 72 in. standard. On sizes larger than 72 in., power traverse is provided on all four heads. The mechanism is foolproof, since the feed and rapid traverse cannot be engaged at the same time, and a safety device is provided against breakage, should the heads accidentally come together. Power traverse of the heads eliminates hand operation and results in a material saving in time and increases the machine output.

FEEDWATER PURIFIED BY EVAPORATION

One of the serious problems of many railroads is to provide some means of softening the feedwater, or in other words, purifying it, to prevent the formation of boiler scale or foaming of the water. One method of purifying water, familiar to every one, is by evaporation, and the application of this method in the marine field has extended over more than 50 years. It was not applied to any extent in stationary power plant practice, however, until about five years ago. It has been claimed that the great advances in power plant efficiency were fostered and first brought out in marine practice, because operation on board ship demands high grade equipment, minimum shutdowns and the greatest ease of repair. As an example of the above statement may be mentioned the purification of boiler feedwater in both large and medium central station plants by means of evaporation. This practice has now been carried on for at least five years, and a special form of device, known as the Reilly evaporator, has been developed by the Griscom-Russell Company, New York.

The purification of boiler feedwater by means of the Reilly evaporator is accomplished in a similar manner to the estab-

lished shipboard procedure, with the exception that the refinements of operation are even greater. The plants are so arranged that practically all of the heat used in the evaporation of the water by the use of steam is returned to the system. In the actual operation, high pressure steam is supplied to the coils of the evaporator and in condensing in these coils, evaporates the body of water in the shell surrounding the coils. This purified vapor is in turn condensed in a condenser and is ready for boiler feed. This is descriptive only of the basic feature of the plant, and it is the utilization of the hot well water as the condensing water, which makes the system not only a valuable means of purification, but an economical practice as well. The main advantage resulting from the use of the Reilly evaporator is the pure feedwater provided, which eliminates scale in the boiler tubes and the necessity of blowing down the boilers.

TWIN MOTOR DRIVEN RADIAL DRILL

A high power plain radial drilling machine which differs radically from the usual design in many respects, has been placed on the market by Joseph T. Ryerson & Son, Chicago, Ill. The machine is designed for heavy duty, and drilling, tapping, boring and reaming operations can be performed with equal efficiency. An attempt has been made to secure the maximum simplicity consistent with the usual range of work performed on radial drills, and only four shafts and 16 gears are used in the machine. The spindle and driving shafts are all contained in a single cast box of rigid construc-

Simplicity in Radial Drill Design is Secured by Twin Motor Drive

tion. Spur gears only are employed, which eliminates bevel gears and the consequent difficulty of keeping them alined.

The head, mounted on SKF ball bearings, travels on the top surface of the arm and is held in alinement with the arm by parallel vees on its under side. Torsional strains are thus largely eliminated. Due to the absence of power transmitting shafts, bevel gears, friction clutches, etc., the drill is unusually quiet in operation. The cross traverse of the head is facilitated by its being carried on ball bearing rollers, adjustable for wear.

A reversing motor is mounted on the head and directly connected to the drive shaft by means of a self-alined,

internally splined coupling. This drive shaft carries a pinion and gear, the pinion being cut integral in the shaft and both run in mesh at all times. The clutch gears are of the conical friction type. The friction cones are mounted on a spacing rod and a movement up or down from the neutral position engages the high or low speed clutch gear. Four other gears are keyed to the clutch shaft and drive the spindle sleeve over change gears on an auxiliary shaft. By shifting the levers, all of which are on the head, the operator engages the desired speed. Sixteen spindle speeds, ranging from 19 to 310 r.p.m. in practically geometrical progression, are obtained in this manner.

For tapping, the motor is reversed, which is instantaneous,

View Showing the Absence of Overhanging Parts and Spindle Travel on a True Radial Line.

and eliminates all shock in the transmission, as well as wear and tear caused by the standard type of friction clutch. The head is completely enclosed and all gears run in oil, a gage indicating the level to the operator.

Feed changes are secured by a cone of gears in connection with a drive key, controlled by a feed-indicating dial and also by engaging in the upper or lower positions a clutch controlled by a lever on the hand-wheel. Two series of eight feeds each, ranging from .005 to .0078 in. and from .0023 to .00370 in. per revolution in practically geometrical progression, are provided. All feeds are disengaged instantly by a friction clutch on the handwheel shaft.

For raising and lowering of the arm, an independent motor of the elevator type is mounted on top of the column. A pinion, keyed directly to the armature shaft, drives a reducing gear on the elevating screw, the thrust of which is taken up by a ball bearing. This composes the entire elevating mechanism and is a very simple arrangement. Limit switches are provided and insure safety. They are equipped with a bracket carrying a roller, which opens the circuit when struck by the sleeve of the arm.

The arm is of box type section, heavily reinforced, and sagging is reduced to a minimum. The center of the spindle is arranged to travel on a radial line, passing through the center of the column. This is stated to be an exclusive feature of the Ryerson-Conradson machine. The arm revolves on ball bearings and means are provided to clamp it securely, a pneumatic clamping device being provided, if desired. The column is provided with an internal web in the line of strain, which greatly increases its rigidity. The base of the machine is surrounded by a deep flange, which materially stiffens it and serves as an oil retainer.

The machine is made in 4-ft., 5-ft. and 6-ft. sizes, drilling to the centers of 8-ft. 1-in., 10-ft. 1-in. and 12-ft. 2-in. circles. To sum up, the advantages claimed for this new radial drill may be stated as simplicity due to twin motor drive, concentration of all shafts in the head, elimination of bevel gears and friction clutches for tapping, exceptional feed range, a spindle operating on a true radial line with the column, and a resulting low power consumption.

JOURNAL COOLING COMPOUND

If it was possible to obtain accurate figures of the direct and indirect costs of cutting out freight cars in this country on account of hot boxes, the total figure would probably be surprisingly large. Some railroads make a direct charge of three dollars each time a car is cut out on account of a hot bearing. Added to this there is indirectly the loss due to

Cleaning Out a Hot Box Preparatory to the Application of Mohawk Cooling Compound

delaying other freight cars, and in case the car cut out is loaded with perishable freight the railroad may be liable for damages.

The estimated cost of removing and reapplying a pair of freight car wheels is six dollars, which together with the cost of machining of \$1.20, makes a total labor cost of \$7.20 on account of each hot box. The total labor cost, plus the charge of three dollars for cutting out, gives a grand total of \$10.20, which may be estimated as the direct cost of a hot bearing.

While it is not maintained that a journal cooling com-

pound can prevent all of the hot boxes and their attendant costs, there is no doubt that if each freight train caboose is provided with a supply of suitable compound, which is used as soon as a bearing shows signs of becoming hot, many hot boxes can be prevented and boxes which do run hot will not necessitate cutting out the car.

A cooling compound in the form of soft grease, which combines the qualities of a lubricant and a cooling compound, has been developed by the Mohawk Lubricating Company, Cincinnati, Ohio, and has worked out so well in practice that several of the roads testing it have arranged for a suitable supply to be carried in each caboose. The illustration shows a typical hot box from which the flaming waste and oil is being removed, preparatory to an application of the above-mentioned cooling compound. The method of application is simply to refill the box with clean waste, placing a liberal supply of compound between the waste and the journal. When placed in contact with a hot journal this compound effervesces, expands, and spreads until it reaches the dry spot on a journal. This lubricates the journal and removes the cause of the heat. Under heavy loads and high speeds, hot boxes are more or less inevitable, but when this cooling compound is applied in time, the hot box is cooled as well as lubricated and there is no delay of the train.

It is stated that the Mohawk cooling compound is not affected by climatic conditions such as heat or cold, a test at 40 deg. below zero proving that the compound will not readily freeze. This is a valuable property, as every one knows who is familiar with the difficulty of starting heavy freight trains in the winter time, due to congealed oil and waste. The compound is stated to be free of acids or any other ingredients that would injure any metal or the employee's hands.

TRANSVEYOR BRAKE ATTACHMENT

A brake attachment has been devised by the Cowan Truck Company, Holyoke, Mass., for use with its transveyor lift truck. The new brake is used to ease heavy loads down inclines and will be found to reduce the manual labor involved, and eliminate the danger of damage to freight caused by the truck getting out of control of its operator. The transveyor lift truck is of the three-wheel type, and the brake attachment illustrated is applied to the single forward wheel. Referring to the illustration, *A* is a pendant swinging from

Brake Arrangement on Cowan Transveyor

the bracket *E* on the transveyor handle. When it is desired to apply the brake, the pendant *A* is allowed to engage in the casting *C*, which is fastened to a strip of spring steel provided with a brake lining on its under side. The greater the pressure brought to bear on the handle, the greater is the braking effect. When it is not desired to use the brake,

the pendant *A* is swung up out of the way, as shown in the dotted position *B*, and is held to the handle by the spring clip *D*. The brake interferes in no way with the ordinary operation of the truck.

NEW DEVELOPMENTS IN THE WHEELER JET CONDENSER

The latest design of vertical jet condenser manufactured by the Wheeler Condenser & Engineering Company, Carteret, N. J., is provided with a vertically split tail pump casing to facilitate repairs. This feature permits easy and quick removal of the pump rotor or other internal part for inspection. It is simply necessary to remove the bolts and cover and uncouple the rotor. Before this design was developed, considerable time was required to get at and remove the rotor.

Temperature fluctuation in the Wheeler condenser is taken care of by the expansion joint between the pump and the

Jet Condenser With Split Tail Pump Casing

condenser body. In some installations the expansion joint is not recommended, hence condensers are made with or without the joint, depending upon the conditions in the plant. The advantage of this form of jet condenser lies in the fact that it utilizes the heat-absorbing capacity of the cooling water to a great degree, discharging it from the bottom of the condenser at practically the same temperature as the steam. At the same time, the outgoing non-condensable gases come into contact with the water entering at the top of the shell, and are therefore cooled to a low temperature.

In operation, referring to the illustration, steam and water

enter at the top. The water is discharged in streams through spiral nozzles, which break up the water current into a rain or spray to insure the desired steam-condensing capacity. The condensed steam and water fall to the bottom of the condenser, where they are removed by the submerged centrifugal pump. The air is removed through an opening just below the cone of the condenser, a small amount of cold water being allowed to fall just in front of the air outlet, thus cooling these gases to their smallest volume. In connection with these condensers, a turbo-air pump or a three-stage steam jet air pump is usually recommended.

AUTOMATIC ARC WELDING MACHINE

Automatic arc welding is accomplished by a device, recently placed on the market by the General Electric Company, Schenectady, N. Y. The welder is for use with the regular welding set, and is designed to take the place of a hand controlled electrode. It consists of a pair of rollers called feed rolls, driven by a small direct current motor, which draw in and deliver to the arc a steady supply of wire, maintaining automatically the best working distance. The machine is controlled from a small panel.

The welding head is held by a suitable support with a certain amount of hand-regulated adjustments and consists of a steel body, carrying feed rolls and straightening rolls,

Increasing the Diameter of a 14-in. Shaft $\frac{3}{8}$ in.

both of which are adjustable for various sizes of wire. The arm is supported on a gear box, together with the motor. This box contains gears which give three gear ratios, thus extending the range of the device while allowing the motor to operate at its most favorable speed.

The control panel carries an ammeter and voltmeter for the welding circuit as well as rheostats, a control relay, and the contactors and switches for the feed motor. It is possible to start and stop the equipment from the work by a pendant push button, but adjustment of the speed conditions must be made from the panel.

The adjustment for arc conditions by regulation of the speed of the feed motor as the arc voltage varies is taken care of by the panel equipment. The result is a steady arc and more uniform and faster work than is possible with a hand-controlled arc.

The whole apparatus is mounted on a base which can be bolted to any form of support. Thus a great variety of working conditions can be met. Provision must be made

for carrying the arc at uniform speed along the weld. For straight seams a lathe or planer bed may be used, and for circular ones a lathe or boring mill, local conditions, of course, dictating the methods to be followed.

The device should be especially valuable where a large amount of routine welding is to be done, as it is claimed that it will operate with from two to six times the speed which can be obtained by skilled welding operators. It is adaptable to welding seams of tanks and plates, rebuilding worn shafts, journals or wheel flanges.

TWENTY-TWO INCH MORRIS ENGINE LATHE

A new 22-in. lathe, provided with a semi-enclosed head-stock and quick change feed box, has been placed on the market by the Morris Machine Tool Company, Cincinnati, Ohio. By means of a patented feed box 45 changes of feed are obtainable, and if desired a semi-quick change feed box may be furnished which provides four positive changes of feed. The quick change and semi-quick change boxes are interchangeable, and provision is made for the use of change gears to cut special pitches or metric threads. A chasing dial also is furnished as standard equipment.

Particular attention has been paid to the design of the carriage, which is of heavy construction, especially in the bridge. The carriage is unusually long and is scraped to a bearing its entire length on the bed. The back of the carriage travels on a flat surface and is held down by a flat gib. The front slides on a large vee and also is gibbed to the bed. The apron is a one-piece box casting, in which all bearings are cast integral. All gears are steel and have bearings at both ends of the shafts. Both feed frictions are operated by a single lever, which is stationary. This overcomes the objection of revolving knurls, or star handles, and permits using the power feed close up to the shoulders. An interlocking arrangement makes it impossible to engage the thread and the feed mechanism at the same time. The rack pinion is heat treated and hardened.

The compound rest regularly furnished with the lathe is

foot. The maximum taper per foot is 4 in., and 25 in. can be turned at one setting of the attachment.

The lathe has a swing over the shears of 23 in. and over the carriage of 15 in. The distance between centers is 3 ft. 6 in. Additional equipment that can be furnished includes a turret on the shears, hand or power feed, a turret on the carriage, a turret toolpost, a pan bed and lubricating outfit.

VACUUM SANDER FOR LOCOMOTIVES

A locomotive sander of simple construction in which the sand is drawn from the dome by the creation of a vacuum instead of being blown by direct air pressure, has been developed by the Fryer Vacuum Sander Company, Tulsa,

The Fryer Vacuum Sander

Okla. The device is arranged for convenience in cleaning should the air nozzle become obstructed or the sand bake at the inlet from the dome.

Referring to the sectional drawing of the sander, it will

22-In. Morris Lathe Provided with Quick Change Feed

provided with a swivel graduated in degrees and clamped by a single bolt through a dovetail clamping ring. A taper attachment can be furnished, which has proved satisfactory under severe cuts. It is graduated in degrees and taper per

be seen that in order to attach it to the locomotive it is only necessary to cut a hole in the side of the sand dome casing of suitable size to receive the end of the sander, the sander then being locked in place by the application of a lock nut

on the inside of the dome. The lower end of the sander casting is fitted for a 1-in. sand pipe connection which is led into the hand sand pipe by the use of a suitable Y fitting a few inches below the hand sander connection to the dome. The installation is completed by the attachment at *G* of a $\frac{1}{4}$ -in. air pipe from the control valve in the cab.

When ready for operation the sand closes the opening *D* into the dome and partly fills the horizontal passage at the left end of the casing, the upward slope of the bottom of the casing preventing it from flowing down the pipe by gravity. On the admission of air pressure at *H*, however, a stream of air is directed downward along the center line of the sand pipe connection through the $\frac{1}{16}$ -in. nozzle *I*, and a vacuum is created between the nozzle and the dome opening. The sand is thus drawn over the point *A* to be caught by the downward flowing stream of air below the nozzle and blown through the pipe to the rail. The device is said to provide complete control of the flow of sand up to its full capacity, which is the equivalent of a $\frac{1}{4}$ -in. stream of sand, by varying the air admitted through the sander valve.

It will be noted that the sand is admitted to the casing through an opening restricted slightly below the size of the air pipe and the remainder of the passage through the sander itself, so that anything which will enter the sander meets no obstruction to its free passage to the rail and the possibility of clogging is thus reduced to the minimum. The employment of the vacuum principle makes possible the elimination of traps or pockets in the sander, thereby greatly reducing the possibility of clogging or freezing in the device itself. Two cleaning plugs are provided at *E* and *F*.

This device has been in successful operation for some time and is now being installed on a large number of locomotives.

STAR GAP LATHE

The use of heavy, expensive tools for the performance of small machine operations is prevalent in too many railway shops. Sometimes this wastefulness and lack of economy is due to carelessness on the part of the operator, who may have a smaller machine available on which the work could be done. In other cases, as for instance when turning an air compressor piston rod with the piston attached, the very

Gap Lathe Developed by the Seneca Falls Manufacturing Company.

nature of the job itself requires that it be performed on a lathe large enough to swing the piston, whereas the diameter of the rod turned is much smaller. In this case the use of some type of gap lathe is economical practice. Owing to the gap feature, a considerably smaller lathe will be of sufficient capacity to swing the piston head, and the larger lathes can be reserved for the heavy machine operations.

The Seneca Falls Manufacturing Company, Seneca Falls,

N. Y., has added to its line of Star screw-cutting lathes two new sizes of gap lathes. These have an 11-in-18-in. swing and a 13-in-21-in. swing, respectively. The bed of the lathe is of the box section type, thoroughly braced by cross webs and heavily reinforced through the gap section to insure accuracy. This feature is well shown in the illustration.

The carriage is provided with a cross slide placed at the left hand for convenience. The cross feed screw is supplied with a micrometer collar, graduated in thousandths of an inch. The apron has a safety device to prevent engagement of the longitudinal feed and the slip nut simultaneously. The lathe has an exceptionally wide range for screw cutting and all standard threads from 3 to 72 per inch can be cut. The standard pipe threads of $11\frac{1}{2}$ and 27 per inch can also be cut. Several attachments can be furnished with the Star gap lathe, including a raising block, quick change gears, taper attachment, motor drive and turrets.

SINGLE MOTOR DRIVEN SURFACE GRINDER

The automatic surface grinding machine illustrated is manufactured by the Diamond Machine Company, Providence, R. I., and a single motor is used to drive both the spindle and the table. Surface grinding machines are sometimes arranged with one motor to drive the spindle, and a second special reversing motor to cause the table to reciprocate. One of the main advantages of the new type of grinding machine illustrated is in the elimination of the special reversing motor. The control switches of such a motor are

Diamond Grinder Equipped with Single Motor Drive

subject to severe service, and it is difficult to get a reversal without more or less shock.

As shown in the illustration, which is a rear view, the initial drive from the motor is through a Morse silent chain and the remainder of the drive is through belting. This is peculiarly adapted to surface grinding machinery, in which smoothness of action is essential to avoid chatter marks on the work. The belt shifting planer type of reversing mechanism provides for smooth running and reverse.

Due to the elimination of the special motor and control box, the grinder can be built at a lower cost. Every precaution is taken to provide against dust and moisture getting into the bearings and careful arrangements are made for the safety of the operator. The water guards are not shown in the illustration, but are furnished with the machine. A guard for the counterweight also is provided.

constructed and the reason for the adoption of that particular feature. The construction of the wheel trucks, the method of supporting the cab, the drawbar connection and the method of drive were points of particular interest to the railway men present.

Fifty-eight years of continuous service with the Grand Trunk is the record of George Clark, foreman of the blacksmith shop at the Stratford works, and he is still attending to his duties with regularity. Mr. Clark entered the service of the Grand Trunk at Point St. Charles in 1862, but he has been stationed at Stratford since 1871.

Director General Hines announced on March 3 that all the equipment that was purchased by the Railroad Administration for the various railroads, consisting of 100,000 freight cars and approximately 1,930 locomotives, has been finally allocated and accepted by the various roads. The Division of Finance advises that where railroads were able and willing to pay for the cost of such equipment in cash, this has been done; that in the other instances the government has accepted the equipment trust obligations of the individual carriers whereby the cost is to be repaid in 15 annual installments at six per cent interest. Equipment trust obligations have been accepted from 74 of the railroad companies.

Locomotive engines should not be operated at so high a rate of speed as to cause such a degree of discomfort to enginemen and firemen as to endanger their health or to impair their efficiency. This is the decision of the New York State Public Service Commission, second district, on a complaint of the brotherhoods that consolidation engines used on the milk trains of the New York, Ontario & Western were unsuitable for the speeds required of those trains. After hearing a good deal of conflicting evidence the commission decided that the engines in question should not be run faster than 30 miles an hour, except under emergencies or unexpected delays, when temporarily the rate might be increased to 35 miles an hour. These speeds must not be permitted except when the engines are in first class condition.

The Plumb Plan League has announced the establishment at its Washington office of a Research Bureau under the direction of O. S. Beyer, Jr. One of the important functions of the bureau will be the keeping of accurate records of all members of Congress for the benefit of their constituents. The speeches, attitudes and votes of Senators and Representatives will be carefully indexed and recorded so that a complete digest of the record of any member of Congress may be secured on short notice. From time to time the bureau will publish special pamphlets, documents, etc., on matters requiring particular illumination. When legislation is pending, or when railroad rate and wage questions are under consideration, the Research Bureau will endeavor to be of help in compiling statistics, arguments and data "for the purpose of proving the justice and soundness of labor's contentions."

Director-General Hines gave a farewell talk to about 200 members of the Railroad Administration staff at the final dinner of the Railroad Administration Lunch Club, of which W. C. Kendall, manager of car service section, has been president, at Washington, on February 25. Mr. Hines paid high tribute to his associates, saying that they had been the hardest working organization he had ever known, and that the team work and lack of friction in an organization brought together under such circumstances was remarkable. He discussed briefly some of the outstanding developments of federal control, saying that large increases in expenses were in no way attributable to federal control, but that the roads would have been subject to them if they had remained under private management and they would not have had the benefit of economies resulting from unification. He pointed out that the Esch-Cummins bill expressly recognizes some

of the advantages of unification and said that while the pendulum will probably swing the other way for a time it will also swing back again and experiences of federal control will have pointed the way.

Because of doubts as to whether Director General Hines and his representatives could continue after March 1 to exercise the authority over the distribution of coal delegated to him by the former fuel administrator, H. A. Garfield, who has since resigned, President Wilson on February 28 issued two executive orders providing for a continuation of Mr. Hines' authority over the "delivery, use, consumption, distribution and apportionment" of coal, and reinstating until April 30, the order of the fuel administrator of November 6, 1917, relative to tidewater transshipment of coal at Hampton Roads, Baltimore, Philadelphia and New York, and for the employment of and co-operation with the Tidewater Coal Exchange, as a common agency to facilitate transshipment and to reduce delays in the use of coal cars and coal carrying vessels, which was suspended on February 20, 1919. J. W. Howe, commissioner of the Tidewater Coal Exchange, Rembrandt Peale, F. M. Whitaker and J. F. Fisher were designated as representatives of the President to carry out the provisions of the order, to exercise the powers of the fuel administrator and also after March 1 the authority vested in the director general of railroads relative to the export of coal from the United States, until April 30.

Boiler Compounds; Their Nature and Use

In the article on boiler compounds, by W. S. Mahlie, published on page 71 of the February issue of the *Railway Mechanical Engineer*, an error occurred in the prices of the chemicals given in Table III. At the top of each column in this table prices were given in dollars, although a footnote to the table stated that prices were in cents. The dollar sign should have been omitted in every case.

Plans for Atlantic City Conventions

The American Railroad Association and the Railway Supply Manufacturers' Association have announced plans for the annual convention to be held in Atlantic City, June 9 to 16, inclusive. The reports of committees of Section III—Mechanical investigating locomotive matters will be received and discussed on Wednesday, Thursday and Friday, June 9, 10 and 11, and reports of committees on car matters will be taken up on Monday, Tuesday and Wednesday of the next week. The sessions of the Mechanical Section will be held in the morning to give time for viewing the exhibits. The Purchases and Stores Section of the American Railroad Association will hold its annual meeting on June 14, 15 and 16, in the Hippodrome.

The Railway Supply Manufacturers' Association has arranged to have exhibits in the balcony over the main building on Young's pier, which will make the total exhibit space approximately 100,000 sq. ft., an increase of 6,500 sq. ft. over 1919. Applications have already been made for practically all the available booths, and a large number of new companies will be represented. All entertainment features will be held on the pier, as was done in 1919.

Erie's Hornell Shops Leased to Private Firm

The Hornell Repair & Construction Company, a concern newly organized for that purpose, on March 6 assumed control of the Erie Railroad shops, roundhouse and car repair yards at Hornell, N. Y. By a contract made on March 1 the new company has leased the shops and will henceforth manage and operate them as a private plant. The officers and employees have been continued in the same positions, the prevailing wage scales, the working conditions and transportation privileges maintained.

The new concern is headed by Hornell business men and its officers consist of Martin F. Woodbury, president; Justin B. Bradley, vice-president; Robert W. Bull, secretary; John F. Nugent, treasurer. Burr L. Smith is a director and Francis M. Cameron attorney.

In the announcement of the step, statements are made that it is hoped that the more direct control of operations will prove more efficient and economical than the former method. It is understood that the shops will be improved and enlarged.

New Reclamation Campaign Instituted on the St. Paul

H. S. Sackett, assistant purchasing agent of the Chicago, Milwaukee & St. Paul, is the author of a new plan being put into effect on the lines of that road, by means of which it is hoped to place reclamation work on a more satisfactory, efficient and economical basis. Mr. Sackett's plan comprises briefly the creation of a system reclamation committee at the road's general headquarters and the establishment of subordinate committees, composed largely of general and division officers, at each of the road's principal shops. The subordinate committees, aided by educational posters, are to supervise local reclamation work, assist in the conduct of educational reclamation campaigns and make studies of the reclamation of various groups of materials.

Mr. Sackett's plan is now being put into operation on the lines of the St. Paul. In the near future it is proposed to hold conferences at Chicago to discuss and develop this reclamation work, and it is proposed thereafter to hold these conferences from time to time and take up the subject of the reclamation of various groups of materials.

Freight Locomotive and Freight Train Costs

The total cost of freight train service, including locomotive service, per 1,000 gross ton-miles, which had been decreasing each month of 1919 up to and including August, showed an increase in September, October, November and December. In December, according to the monthly report of the Operating Statistics Section of the Railroad Administration, it was 139.7 cents, as compared with 124.4 cents in December, 1918, and as compared with 122 cents in November, 1919. In October it was less than for October, 1918. Per locomotive-mile and per train-mile in December the cost was also greater than in December, 1918. The cost of freight locomotive service per locomotive-mile in December was 131 cents, as compared with 121.1 cents in December, 1918. In November it was 119.7 cents. The cost of freight train service per train-mile in December was 185.2 cents, as compared with 171.3 cents in December, 1918. In November it was 170.3 cents. The combined figures for all regions and the comparative figures for 1918 are as follows: (Costs for 1918 have been readjusted for back pay, while the costs for 1919 apply to the month of November only, the back pay applicable to previous months having been eliminated.)

	December	
	1919	1918
Cost of locomotive service per locomotive-mile....(cents)	130.0	121.1
Locomotive repairs	41.6	39.0
Enginehouse expenses	9.3	10.1
Train enginemmen	22.3	19.3
Locomotive fuel	53.8	48.6
Other locomotive supplies	3.9	4.0
Cost of train service per train-mile.....	185.2	171.3
Locomotive repairs	57.9	56.4
Enginehouse expenses	61.2	55.8
Other locomotive supplies	4.4	4.6
Train enginemmen	25.3	22.2
Trainmen	28.8	25.6
Train supplies and expenses.....	7.6	6.7
Cost of total train service per 1,000 gross ton-miles.....
Locomotive repairs	43.7	41.0
Enginehouse expenses	46.2	40.5
Other locomotive supplies.....	3.3	3.4
Enginemmen and trainmen	40.8	34.7
Train supplies and expenses.....	5.7	4.9

MEETINGS AND CONVENTIONS

Western Railway Club.—At the April 19, 1920, meeting of the Western Railway Club a paper will be presented by S. W. Mullinix, superintendent of shops of the Chicago, Rock Island & Pacific on Modern Methods of Reducing Cost of Locomotive Repairs.

Master Tinnners', Coppersmiths' and Pipefitters' Association.—The sixth annual convention of this association will be held at the Hotel Sherman, Chicago, June 1-4, 1920. Foremen who are not members of the association are also invited to be present at the meeting.

Storekeepers' Annual Meeting.—Section VI, American Railroad Association—Department of Purchases and Stores—will hold its first annual meeting at Atlantic City, N. J., on June 14, 15 and 16. Headquarters will be at the Marlborough-Blenheim Hotel and business sessions will be held in the Hippodrome on the Million Dollar pier.

Members and all persons attending are asked to reach Atlantic City by Saturday, June 12, if possible, in order to see the exhibits and not be obliged to take time from business sessions for that purpose. Badges must be secured, on arrival, from the committee at the pier.

Seventeen subjects are on the program for discussion, as follows, the name of the chairman of the committee in charge being given with each subject:

1. Store department book of rules; J. G. Stuart (C. B. & Q.).
2. Classification of material; C. H. Rost (C. R. I. & P.).
3. Reclamation of material.
4. Material accounting; W. E. Brady (A. T. & S. F.).
5. Commissary; G. C. Smith (U. P.).
6. Cross ties; J. H. Waterman (C. B. & Q.).
7. Stationery; W. D. Stokes, supervisor of stores, United States Railroad Administration, Southern Region.
8. Distribution of material to users; W. D. Stokes.
9. Fuel—purchasing, storage and distribution; S. B. Wright (N. Y. C.).
10. Scrap; handling and sales; G. W. Hayden (N. Y., N. H. & H.).
11. Ice—purchasing, storage and distribution; T. I. Frier (Wabash).
12. Purchasing agent's office records; C. E. Walsh (P. W. P.).
13. Lumber; Wm. Beatty (P. R. R.).
14. Rails; A. A. Goodchild (C. P. R.).
15. Buildings and structures; U. K. Hall, associate manager, stores section, United States Railroad Administration.
16. Supply train operation; A. S. McKelligon (S. P.).
17. Standards; F. D. Reed (C. R. I. & P.).

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

- AIR-BRAKE ASSOCIATION.**—F. M. Nellis, Room 3014, 165 Broadway, New York City. Convention May 4-7, Hotel Sherman, Chicago.
- AMERICAN RAILROAD ASSOCIATION, SECTION III.—MECHANICAL.**—V. R. Hawthorne, 431 South Dearborn St., Chicago. Convention, June 9-16, 1920, Atlantic City, N. J.
- AMERICAN RAILROAD ASSOCIATION, SECTION VI—PURCHASES AND STORES.**—J. P. Murphy, N. Y. C., Collinwood, Ohio. Convention June 14-16, 1920, Atlantic City, N. J.
- AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.**—O. E. Schlink, 485 W. Fifth St., Peru, Ind. Convention June 1-4, 1920, Hotel Sherman, Chicago.
- AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.**—R. D. Fletcher, Belt Railway, Chicago.
- AMERICAN SOCIETY FOR TESTING MATERIALS.**—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 21, 1920, New Monterey Hotel, Asbury Park, N. J.
- AMERICAN SOCIETY OF MECHANICAL ENGINEERS.**—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
- AMERICAN STEEL TREATERS' SOCIETY.**—W. H. Eisenman, 154 E. Erie St., Chicago.
- ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.**—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.
- CAR FOREMEN'S ASSOCIATION OF CHICAGO.**—Aron Kline, 626 North Pine Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.
- CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.**—Thomas B. Koeneke, secretary, Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
- CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.**—J. C. Keene, Decatur, Ill.
- INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.**—A. L. Woodworth, C. H. & D., Lima, Ohio.
- INTERNATIONAL RAILWAY FUEL ASSOCIATION.**—J. G. Crawford, 542 W. Jackson Blvd., Chicago. Convention, May 24-27, 1920, Hotel Sherman, Chicago, Ill.
- INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.**—William Hall, 1061 W. Wabasha Ave., Winona, Minn.
- MASTER BOILERMAKERS' ASSOCIATION.**—Harry D. Vought, 95 Liberty St., New York. Convention May 25-28, Curtis Hotel, Minneapolis, Minn.
- MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION OF U. S. AND CANADA.**—A. P. Dane, B. & M., Reading, Mass.
- NIAGARA FRONTIER CAR MEN'S ASSOCIATION.**—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Stabler Hotel, Buffalo, N. Y.
- TRAVELING ENGINEERS' ASSOCIATION.**—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

PERSONAL MENTION

GENERAL

F. W. BRAZIER has been appointed assistant to the general superintendent of rolling stock of the New York Central, with headquarters in New York.

A. E. CALKINS, engineer of rolling stock for the corporate organization of the New York Central under federal control, has been appointed superintendent of rolling stock for the Eastern Lines, with headquarters at New York.

J. T. CARROLL, general superintendent maintenance of equipment, with headquarters at Baltimore, Md., has had his title changed to general superintendent of motive power.

ROBERT COLLETT, assistant manager of the Fuel Conservation section of the Railroad Administration, during federal control, has been appointed superintendent of fuel and locomotive performance of the New York Central.

GEORGE T. DEPUE, who has been appointed mechanical superintendent of the newly created Chicago region of the Erie, was born on December 2, 1872, in Hornell, N. Y., and received his education in the grammar schools.

On March 1, 1889, he entered the employ of the Erie as a machinist apprentice. After that he worked as a machinist and extra gang foreman until March 1, 1901, when he was promoted to the position of general foreman of the Bradford division, with headquarters at Bradford, Pa. On August 1, 1901, he was appointed general foreman of the Hornell shop; on July 1, 1903, master mechanic at Hornell; on April 1, 1908, master mechanic at Galion, Ohio; and on August 1, 1913, shop superintendent at Galion, holding that position until July 1, 1916, when he was appointed shop superintendent at Susquehanna, Pa. This is the position he left on March 1, 1920, when the Erie was reorganized and he was appointed mechanical superintendent of the Chicago region.

THOMAS W. DEMAREST, who has been appointed general superintendent motive power of the Northwestern region of the Pennsylvania, with headquarters at Chicago, was born on March 18, 1868, at Englewood, N. J., and was graduated from Stevens Institute of Technology at Hoboken, N. J., on June 4, 1888. Mr. Demarest began railroad work as a special apprentice in the shops of the Pittsburgh, Cincinnati & St. Louis at Columbus, Ohio. He was later assistant to the master mechanic at Columbus, and on February 1, 1897, was appointed general foreman of the locomotive department of the same shops. He was promoted to master mechanic at the Logansport, Ind., shops on August 1, 1899, and on January 1, 1900, was appointed superintendent motive power of the Pittsburgh, Cincinnati, Chicago & St. Louis. From July, 1903, to March 1, 1920, he was superintendent motive power of the Northwest system of the Pennsylvania Lines West, his headquarters for some years past having been at Pittsburgh, Pa.

G. T. Depue

J. J. DOWLING, general master mechanic of the Eastern district of the Great Northern, with office at St. Paul, Minn., has been appointed superintendent of motive power of the lines west, with headquarters at Spokane, Wash.

G. L. LAMBETH, master mechanic of the Mobile & Ohio at Whistler, Ala., has been appointed superintendent of motive power and car equipment, with headquarters at Mobile, Ala., succeeding J. J. Thomas, Jr., resigned.

EDWIN B. DEVILBISS, who on March 1, 1920, was appointed superintendent motive power of the Eastern Ohio division, Central region, of the Pennsylvania System, was born on September 13,

1884, at Fort Wayne, Ind. He was graduated from Purdue University in 1908 with the degree of mechanical engineer and entered the employ of the Pennsylvania Lines West on July 1, 1908, as a special apprentice. He was promoted to motive power inspector on January 1, 1911, to electrical engineer of the Northwest system on April 1, 1912, and to assistant engineer of motive power of the Central system on June 1, 1915. At the

time of his recent appointment he was assistant engineer of motive power in the office of the general superintendent of motive power of the Lines West, at Pittsburgh, Pa., having held that position since October 15, 1917.

GEORGE H. EMERSON has been appointed chief of motive power and equipment of the Baltimore & Ohio, with headquarters at Baltimore, Md. Mr. Emerson entered railway service in 1880 as a water boy on the Willmar division of the Great Northern. From 1882 to 1887 he served an apprenticeship at the St. Paul shops, afterwards until 1897 acting consecutively as boilermaker, fireman, engineman and locomotive foreman. From 1897 to 1900 he was general shop foreman and master mechanic of the Dakota and Northern divisions. On the latter date he was appointed general master mechanic of the Western district, and in 1903 superintendent of motive power. He was made assistant general manager of the Great Northern on March 15, 1910, and on October 1, 1912, was appointed general manager. In October, 1917, he left the service of the Great Northern to take charge of the Russian Railway Service Corps, receiving the commission of colonel.

B. J. FARR, superintendent of the motive power and car department of the Grand Trunk Western Lines, has moved his headquarters from Detroit, Mich., to Battle Creek.

FRANK H. HARDIN, assistant to the federal manager of the New York Central, has been appointed chief engineer of motive power and rolling stock, with headquarters in New York. Mr. Hardin was born on June 14, 1886, in Gainesville, Ga. He was graduated from the Georgia School of Technology in 1908 and then took a post graduate course at Columbia University. All his railroad service has been with the New York Central, he having begun on August 1, 1909, as a special apprentice at the West Albany shops. After several minor promotions, he was made enginehouse foreman at Tupper Lake, N. Y., in June, 1913, and in November of that year was transferred to Utica, N. Y., as assistant foreman, where he remained for one year, until

E. B. DeVilbiss

November, 1914. At that time he was appointed special engineer in the office of the assistant to the president in New York. From March, 1917, to November, 1918, he was master mechanic of the Adirondack division, with headquarters in Utica. On the latter date he was appointed assistant to the federal manager of the New York Central at New York, holding that position until March 1, 1920.

W. C. A. HENRY, who has been appointed general superintendent of motive power of the Southwestern region of the Pennsylvania, with headquarters at St. Louis, Mo., was

W. C. A. Henry

born on October 13, 1873, at Stapleton, Staten Island, N. Y., and was educated at Brooklyn Polytechnic Institute. He started work as a special machinist apprentice with the Pennsylvania at Altoona on March 2, 1891, and on June 1, 1897, was made acting foreman of car inspectors on the Pittsburgh division, afterwards acting consecutively as assistant road foreman of engines, assistant general foreman of the car shop at Altoona, and assistant engineer of motive power until July, 1903, when he was appointed master mechanic at Wellsville, Ohio, on May 1, 1906, being transferred to Columbus, Ohio. From September, 1906, to March 1, 1920, Mr. Henry was superintendent of motive power of the Southwest system of the Pennsylvania Lines West, with headquarters at Columbus, Ohio.

FREDERICK W. HANKINS, who was appointed assistant chief of motive power (locomotive), with headquarters at Philadelphia, Pa., when the Pennsylvania was reorganized, was born on January 1, 1876, at London, England. Mr. Hankins was educated in the public schools of Foxburg, Pa., and entered the service of the Pittsburgh & Western, then part of the Baltimore & Ohio, as a machinist apprentice in April, 1891. He was transferred to the Baltimore & Ohio at Allegheny, Pa., in 1894, and in July, 1897, entered the employ of the Allegheny Valley at the Forty-third street shops in Pittsburgh, Pa., where he served successively as machinist, leading machinist and acting roundhouse foreman until April, 1905, when he was transferred to the Cumberland Valley as enginehouse foreman at Chambersburg, later being machine shop foreman and general foreman until about June, 1916, when he was appointed master mechanic. Early in 1919 Mr. Hankins was transferred to Altoona, Pa., as master mechanic of the Pennsylvania, and held that position until March 1, 1920. Mr. Hankins' present headquarters are at Philadelphia, Pa., instead of at Atlanta, as stated on page 181 of the March *Railway Mechanical Engineer*.

WILLIAM KELLY, assistant superintendent motive power of the Great Northern, has been appointed general superintendent of motive power, with headquarters at St. Paul, Minn., succeeding A. C. Deverell.

R. L. KLEINE, formerly chief car inspector of the Pennsylvania, with office at Altoona, Pa., who since March 1, 1920, has been assistant chief of motive power (car), now has his headquarters in Philadelphia, Pa., instead of Altoona, as it was incorrectly given in the list of officers published on page 181 of the March *Railway Mechanical Engineer*.

W. F. KUHLMKE, master mechanic of the Charleston & Western Carolina, with headquarters at Augusta, Ga., has been appointed superintendent motive power, with the same headquarters.

L. P. MICHAEL, chief draftsman in the motive power and car departments of the Chicago & North Western, has been appointed mechanical engineer with headquarters in Chicago, succeeding J. C. Little, resigned.

B. J. PEASLEY, superintendent motive power of the Vicksburg, Shreveport & Pacific at Monroe, La., has been appointed superintendent motive power of the St. Louis Southwestern, with office at Tyler, Tex. A photograph of Mr. Peasley and a sketch of his railroad career were published in the *Railway Mechanical Engineer* for December, 1919, on page 749.

C. G. SLAGLE, assistant mechanical engineer of the Cincinnati, Indianapolis & Western, has been appointed acting superintendent motive power, with headquarters at Indianapolis, Ind.

C. E. PECK, assistant superintendent motive power of the Oregon-Washington Railroad & Navigation Company, has been appointed superintendent motive power and machinery, succeeding J. F. Graham, deceased.

J. W. SENGER, master car builder of the New York Central Lines west of Buffalo, with headquarters at Collinwood, Ohio, has been appointed superintendent of rolling stock of the Lines West, with headquarters at Buffalo, N. Y.

P. F. SMITH, JR., who has been appointed works manager of the Pennsylvania at Altoona, was born on August 1, 1870. After graduating from Warrall's Technical Academy in

P. F. Smith, Jr.

June, 1887, he was employed by the Pennsylvania as an apprentice in the shops at Altoona, Pa. After several minor promotions he was appointed assistant road foreman of engines on the Pittsburgh division in February, 1892. On February 1, 1895, he was appointed assistant master mechanic at the Fort Wayne, Ind., shops, and in November, 1896, was promoted to the position of master mechanic of the Crestline, Ohio, shops and the Toledo division. From January 1, 1900, to December 31, 1911, he was master mechanic at several shops of the Pittsburgh, Cincinnati, Chicago & St. Louis, and on January 1, 1912, was appointed superintendent of motive power of the Central system, Pennsylvania Lines West, which position he held until January, 1917, when he was appointed general superintendent of motive power of the Lines West, with headquarters at Pittsburgh, Pa. When the Pennsylvania system was reorganized on March 1, Mr. Smith was appointed works manager of the Altoona shops, reporting direct to J. T. Wallis, the chief of motive power, with the authority and responsibility that the manager of an industrial manufacturing plant would have.

R. PORTER SMITH, chief draftsman of the Georgia Railroad, has been appointed mechanical engineer of that road, the Atlanta & West Point and the Western Railway of Alabama, with headquarters at Augusta, Ga. Mr. Smith

was born on January 3, 1875, at Olean, N. Y., and received his education in the public schools there, entering railway work in February, 1899, with the Western New York & Pennsylvania at Olean. When that road became part of the Pennsylvania he continued with it, being employed in the boiler, machine and erecting shops until August, 1901. He was then transferred to the drawing room, remaining there until October, 1903, when he was appointed roundhouse foreman, resigning in February, 1906, to go with the Georgia Railroad as chief draftsman. He acted in that capacity continuously from April 2, 1906, until March 1, 1920, the time of his recent appointment as mechanical engineer.

J. J. TATUM, general supervisor of car repairs for the United States Railroad Administration, has returned to the service of the Baltimore & Ohio, as superintendent of the car department, having headquarters at Baltimore, Md.

F. O. WALSH has been appointed superintendent of motive power of the Atlanta & West Point, the Western Railway of Alabama and the Georgia Railroad, with headquarters at Atlanta, Ga.

W. O. THOMPSON, superintendent of rolling stock of the New York Central Lines west of Buffalo, with headquarters at Cleveland, Ohio, has been appointed general superintendent of rolling stock, with office at Buffalo, N. Y. Mr. Thompson was born in Clayton, Mich., in 1863 and was graduated from Adrian (Mich.) high school. He began railroad work in 1882 on the Fort Wayne, Jackson & Saginaw, which later became a part of the Lake Shore & Michigan Southern. From 1884 to 1890 he served as a locomotive engineman and then was appointed traveling engineer, remaining in that position until August, 1893. He was then for some years an engine despatcher and in 1901 was appointed general locomotive inspector of the New York Central & Hudson River. The following year he was appointed superintendent of motive power on the Rome, Watertown & Ogdensburg division, and in 1907 became district master car builder at East Buffalo, N. Y. He was appointed superintendent of rolling stock of the New York Central Lines West of Buffalo during 1915, from which position he was recently promoted to general superintendent of rolling stock for the entire system.

W. O. Thompson

HENRY YOERG, assistant superintendent motive power of the Great Northern, has been appointed superintendent motive power of the lines east, with headquarters at St. Paul, Minn. Mr. Yoerg was born on June 17, 1872, at St. Paul, Minn., and was graduated from Massachusetts Institute of Technology, in the class of 1895. He began railway work in 1897 as a draftsman on the Great Northern, afterwards being consecutively assistant engineer, superintendent of the machine shops at Havre, Mont., and superintendent of machine and car shops at St. Paul, until 1908, when he was advanced to the position of mechanical engineer. During 1917 he was appointed assistant superintendent of motive power, with headquarters at St. Paul, which position he held until his recent appointment.

J. M. HENRY, who has been appointed general superintendent of motive power of the Eastern region of the Pennsylvania, with headquarters at Philadelphia, Pa., was born on October 10, 1873.

He entered the service of the Pennsylvania Railroad as a special apprentice in the Altoona machine shops on May 5, 1889, and served as an apprentice until September 1, 1896, when he entered Purdue University, being furloughed from the shops during the school term each year. He was graduated in June, 1900, and then became a special apprentice in the office of the assistant engineer of motive power at Altoona. A year later he

was promoted to motive power inspector at Altoona, and in February, 1902, was made assistant engineer of motive power of the Erie division and Northern Central Railway at Williamsport, Pa. From July 1, 1903, to December, 1913, he was master mechanic at various shops. On the latter date he was promoted to superintendent of motive power of the Western Pennsylvania division, and on May 1, 1916, was transferred to the operating department as assistant superintendent of the Pittsburgh division, on April 15, 1917, being transferred to the New York division. About October of that year he was appointed assistant general superintendent of motive power at Altoona, holding that position until March 1, 1920, when he was appointed one of the four regional general superintendents of motive power.

AMOS C. DAVIS, who has been appointed superintendent motive power of the Southern division, Eastern region, of the Pennsylvania system, was born on March 20, 1876, in Altoona, Pa., and received

his education in public and private schools in Indiana county, Pa. His entire railroad service, dating from April 3, 1893, has been with the Pennsylvania, his first position being that of machinist apprentice at the Altoona shops. At the end of his apprenticeship he was employed as a machinist for about two years and was then made gang leader in the erecting shop. After several minor promotions he was appointed acting assistant master

A. C. Davis

mechanic at Altoona on March 8, 1909, and on April 1, 1910, foreman of the miscellaneous shop. For five years from July, 1912, to July, 1917, he was general foreman of the locomotive erecting shop at Altoona, on the latter date being made general foreman at East Altoona, and in October of that year was appointed general foreman of the Altoona machine shop. On October 21, 1918, Mr. Davis was appointed master mechanic of the Maryland division, with headquar-

J. M. Henry

ters at Wilmington, Del., holding this position at the time of the recent reorganization of the Pennsylvania system.

H. H. MAXFIELD, who works manager of the Pennsylvania Railroad at Altoona, Pa., has been appointed one of the four regional general superintendents of motive power, having jurisdiction over the Central region, with headquarters at Pittsburgh, Pa. A photograph of Mr. Maxfield and a sketch of his railroad career were published in the *Railway Mechanical Engineer* for September, 1919, on page 561.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

FRANK J. DAILEY has been appointed assistant master mechanic of the Erie at Dunmore, Pa.

ALBERT J. DAVIS, formerly master mechanic of the Erie at Jersey City, N. J., and recently shop superintendent at Galion, Ohio, has again been appointed master mechanic at Jersey City, succeeding F. H. Murray.

M. J. FLANIGAN, master mechanic of the Great Northern at Everett, Wash., has been appointed general master mechanic of the Eastern district, with office at St. Paul, Minn., succeeding J. J. Dowling.

J. B. IRWIN, master mechanic of the Chicago, Burlington & Quincy at Casper, Wyo., has been transferred to Alliance, Neb., succeeding G. E. Johnson.

G. E. JOHNSON, master mechanic of the Chicago, Burlington & Quincy at Alliance, Neb., has been appointed master mechanic at Sheridan, Wyo., succeeding F. E. Kennedy deceased.

GEORGE C. JONES has been appointed general road foreman of engines of the Atlantic Coast Line, with headquarters at Florence, S. C.

C. E. MELKER has been appointed acting master mechanic of the Chicago, Burlington & Quincy at Casper, Wyo., succeeding J. B. Irwin.

ROY R. HERRICK, whose appointment as master mechanic of the Detroit, Bay City & Western, with headquarters at Bay City, Mich., was announced in these columns last month,

was born on November 25, 1890, at Jackson, Mich., and was educated in the public schools of Jackson. He has been engaged in railroad work since the spring of 1908, when he took employment with the Michigan Central as a machine operator in the shops at Jackson. Later he was transferred to the roundhouse as an air brake repairman, and then to the passenger terminal at Kalamazoo, Mich. Two years later he returned to

the roundhouse at Jackson, where he was employed as a machinist. On January 1, 1918, he went with the Detroit, Bay City & Western, and was recently appointed master mechanic.

EVERETT O. SMITH, whose appointment as master mechanic of the Louisiana & North West, with office at Homer, La., has already been announced in these columns, was born at Chicopee, Mass., and was educated in the public schools of Marshalltown, Iowa. He has been engaged in railroad work since July 1, 1882, when he entered the employ

of the Iowa Central as a machinist apprentice. In April, 1883, he went to the Chicago shops of the Chicago & North Western and was made gang foreman in 1887. In 1894 he was promoted to the position of foreman of shops at Belle Plaine, Iowa, and was later transferred in that capacity to Council Bluffs, Iowa, and West Chicago, Ill. In 1902 he became general foreman of the Iowa, Illinois & Indiana Railway at Kankakee, Mich., and in 1903 accepted the position of master mechanic of the St. Louis & Hannibal at Hannibal, Mo., which he held continuously since that time until he received his recent appointment on the Louisiana & North West.

HARRY F. MARTYR, formerly general foreman of the locomotive shops of the Chicago, Rock Island & Pacific at Horton, Kan., has been appointed master mechanic of the

H. F. Martyr

St. Louis & Hannibal, with office at Hannibal, Mo. Mr. Martyr was born on August 9, 1876, at Cosgrove, England. In 1890 he entered the employ of the London & Northwestern as a machinist apprentice. He came to America in September, 1897, and took employment with the Missouri Pacific as a machinist. He was later employed by the St. Louis-San Francisco as machine shop foreman, roundhouse foreman and general foreman. From 1907

to 1911 he was general foreman of the locomotive and car departments of the Detroit, Toledo & Ironton at Jackson, Ohio, and for the last eight years was with the Chicago, Rock Island & Pacific, his last position with that road being general foreman of the locomotive shops at Horton, Kansas. During the latter part of 1919 he was appointed master mechanic of the St. Louis & Hannibal.

J. A. WRIGHT, general foreman on the Chicago, Milwaukee & St. Paul, has been appointed division master mechanic at Tacoma, Wash., succeeding G. E. Cessford,

transferred to a similar position at Bellingham, Wash. Mr. Wright was born on June 8, 1880, at Foxburgh, Pa. He received his education in the public schools of Kansas City, Kan., and also attended Puget Sound University, Tacoma, Wash. In 1899 he began railroad work as a fireman on the Northern Pacific. He later served a machinist apprenticeship on the Tacoma Eastern, and then worked as machinist, locomotive fireman and engine-

J. A. Wright

man on that road, until 1910, since which time he has been with the Chicago, Milwaukee & St. Paul, latterly as roundhouse foreman and general shop foreman.

R. R. Herrick

CAR DEPARTMENT

ALFRED HERBSTER, division general foreman of the car department of the New York Central, Lines West of Buffalo, at Englewood, Ill., has been appointed assistant master car builder of the Fourth district, Western Lines, with the same headquarters.

JAMES REED, assistant master car builder of the New York Central, Lines West of Buffalo, with headquarters at Englewood, Ill., has been appointed master car builder of the Fourth district, Lines West, with the same headquarters at Englewood.

GEORGE THOMSON, master car builder of the New York Central Lines West, with headquarters at Englewood, Ill., is now master car builder of the Third district, Lines West, with headquarters at Collinwood, Ohio.

SHOP AND ENGINEHOUSE

JAMES A. ANDERSON has been appointed shop superintendent of the Chicago, Milwaukee & St. Paul at Milwaukee, Wis., succeeding A. N. Lucas, resigned. Mr. Anderson was born at Delas Island, Md., July 9, 1883. He completed his education at the Maryland State College, graduating with the degree of mechanical engineer in 1904, and entered the service of the Baltimore & Ohio as a special apprentice at the Mount Clair shops. He completed his special apprenticeship in 1906 and served as a material inspector in the test bureau until early in 1907, when he was transferred to Garrett, Ind. Here he served successively as a machinist, assistant foreman and roundhouse foreman until March, 1909, then being transferred to Holloway, Ohio, as general foreman of the locomotive and car department. In April, 1912, Mr. Anderson was transferred to Wheeling, W. Va., as motive power inspector, and about a year later was promoted to assistant road foreman of engines. In April, 1914, he was appointed master mechanic of the Cleveland division of the Baltimore & Ohio, continuing in this capacity until July, 1916, when he was transferred to Grafton, W. Va., as master mechanic of the Monongah division. After a little more than two years at Grafton, Mr. Anderson was transferred to the Wheeling division, with headquarters at Benwood, W. Va., where he served as master mechanic until July, 1919. He was then transferred to the Baltimore & Ohio shops at Pittsburgh, Pa., and appointed assistant superintendent in charge of the locomotive department. He continued in the service of the Baltimore & Ohio in this capacity until February 1, 1920, when he left to enter the service of the Chicago, Milwaukee & St. Paul, as shop superintendent at Milwaukee.

FREDERICK H. MURRAY, master mechanic of the Erie at Jersey City, N. J., has been appointed shop superintendent at Susquehanna, Pa., succeeding G. T. Depue, recently appointed regional mechanical superintendent of the Chicago region.

PURCHASING AND STOREKEEPING

C. S. MARSHALL has been appointed general storekeeper of the St. Louis Southwestern, with headquarters at Tyler, Tex.

OBITUARY

W. R. SHOOP, manager of purchases and stores of the Buffalo, Rochester & Pittsburgh, with headquarters in Rochester, N. Y., died recently at his home in Rochester. He was 65 years old.

J. F. GRAHAM, superintendent of motive power of the Oregon-Washington Railroad & Navigation Company, with headquarters at Portland, Ore., died recently at his home in that city at the age of 71 years.

SUPPLY TRADE NOTES

E. G. Middleton has been appointed advertising manager of the Colburn Machine Tool Company, Franklin, Pa., manufacturer of vertical boring mills and heavy-duty drilling machines.

W. S. Atkinson, for many years purchasing agent for the Kansas City Southern, has been appointed manager of the railway sales department of the Cook Paint & Varnish Company, Kansas City, Mo.

A. G. Williams, manager of the export department of the American Steel Foundries, Chicago, Ill., sailed from Seattle, Wash., on March 1 for China and Japan, to develop new business in those countries.

Duncan W. Fraser, managing director of the Montreal Locomotive Works, Ltd., on March 1, 1920, was elected vice-president in charge of sales of the American Locomotive Company and vice-president

D. W. Frazer

in charge of domestic sales of the Montreal Locomotive Works, Ltd., with headquarters at New York, succeeding J. D. Sawyer, who has resigned to become vice-president of the banking firm of Morton & Co., Inc. Mr. Fraser was born in Pictou county, Nova Scotia, Canada, in 1875, of Scotch ancestors. He was educated in Nova Scotia public schools and at the age of 18 went to Providence, R. I., where he served a four-year ap-

prenticeship course in the shops of the Rhode Island Locomotive Works, later the Providence plant of the American Locomotive Company. With the exception of three years in the service of the Brown & Sharpe Manufacturing Company, Providence, R. I., he continued in the service of the locomotive works until 1904. In that year the Montreal Locomotive & Machine Company, of Montreal, was bought by the American Locomotive Company, and Mr. Fraser was transferred to that plant, serving consecutively as gang boss, sub-foreman and assistant foreman, until 1906, when he was appointed general foreman of the machine departments. In 1908 he was appointed assistant superintendent and later served as superintendent, until December, 1910, when he was made works manager. On February 15, 1917, he was appointed general manager of the Montreal Locomotive Works, Ltd., in charge of sales and manufacturing, and in November, 1919, he was appointed managing director of that company.

The Cincinnati Automatic Machine Company, Cincinnati, Ohio, has purchased from the Windsor Machine Company, Windsor, Vt., the manufacturing, selling and patent rights of the Gridley automatic multiple drilling machine.

At a recent meeting of the stockholders of the Buffalo Forge Company, Buffalo, N. Y., new officers were elected as follows: Henry W. Wendt, president; Edgar F. Wendt, vice-president and treasurer; Henry W. Wendt, Jr., vice-president and secretary; C. A. Booth, vice-president and sales man-

ager. The new directors include the above named officers and in addition H. S. Whiting.

Leslie R. Pyle, supervisor of the Fuel Conservation Section of the United States Railroad Administration, with office at Chicago, has been elected vice-president of the Locomotive Firebox Company, Marquette building, Chicago.

Franklin Murphy, former governor of New Jersey and chairman of the board of directors of the Murphy Varnish Company, Newark, N. J., died on February 24, at Palm Beach, Fla. He was born in Jersey City, on January 3, 1846, and was educated in the Hudson county schools and at Newark Academy. In 1901 he received the degree of doctor of laws from Lafayette College and the following year the same degree from Princeton University. Mr. Murphy served in the United States army during the Civil War, part of the time as a lieutenant; at the close of hostilities he began the manufacture of varnish at Newark, N.

F. Murphy

J. In 1891 the Murphy Varnish Company was incorporated, with Mr. Murphy as president. He had been prominent in Republican politics since 1892, and in 1901 was elected to the governorship of New Jersey, which office he held for three years. His son, Franklin Murphy, Jr., is now chairman of the executive committee of the Murphy Varnish Company.

Galena Signal Oil Company Elects New Officers

At the annual meeting of the Galena Signal Oil Company, Franklin, Pa., on February 24, L. J. Drake was elected president to succeed J. S. Cullinan, and W. A. Trubee, district manager at New York, and W. J. Walsh, district manager at Chicago, were elected vice-presidents, all with

Lauren J. Drake, the new president, with headquarters at New York, was born on August 27, 1880, at Keokuk, Iowa. He was educated in the public schools of Omaha and Chicago, and in 1899 graduated from Shattuck Military School, Faribault, Minn. After leaving school he entered the oil business and acquired a general knowledge of it in all departments during his service of five years with several companies. In 1905 he went to the Galena Signal Oil Company and remained as a representative of that company in the Middle West, until 1916, when he came to New York as vice-president.

W. A. Trubee was born in Bridgeport, Conn., on March 22, 1867. He received his early education in Bridgeport private schools, and later attended Greylock Institute at South Williamstown, Mass. He entered the service of the Galena-Signal Oil Company on February 1, 1898, as sales representative at Bridgeport, Conn. On May 1, 1912, he was transferred from Bridgeport to the New York office, and on March 1, 1919, was appointed district manager at New York, which position he held until his recent election as vice-president and director of the same company.

The Mono Corporation of America, 48 Coal and Iron Exchange, Buffalo, N. Y., announces that it has purchased the entire stock of Mono apparatus and accessories from the F. D. Harger Company, Buffalo, N. Y., including all rights for the manufacture and sale of Mono apparatus for the automatic analysis of CO₂, CO and other gases.

H. G. Cook, formerly general storekeeper of the Southern Pacific Company, San Francisco, has entered the railway supply business and opened offices in San Francisco, Cal., representing the following companies on the Pacific Coast: Union Asbestos & Rubber Manufacturing Company, Dearborn Chemical Company, Chicago Railway Equipment Company, Bradford Draft Gear Company, Pyle National Headlight Company, National Waste Company.

Improvements and remodeling to cost approximately \$3,500,000 are being carried out at the car works of the Pullman Company. The improvements include a new three-story building of mill construction and a new press building, 80 ft. by 200 ft. The old foundry buildings are being remodeled to furnish additional space. The purpose of the improvements is to provide adequate facilities for the manufacture of automobile bodies.

L. J. Drake

W. J. Walsh

W. A. Trubee

the same headquarters as formerly. L. F. Jordon remains as vice-president at New York and J. E. Linahen as vice-president at Franklin; J. French Miller as secretary-treasurer at Franklin, L. E. Stull assistant secretary and assistant treasurer at Franklin, and C. W. Hochette assistant secretary and assistant treasurer at New York.

The Allegheny Steel Tank Car Company, Warren, Pa., was bought by the Allegheny Tank Car Company on February 2. The new corporation was recently formed and the transfer constituted an entire change of management. The officers of the new company are as follows: C. W. Hardy, formerly of the Warren Oil Company, Warren, Pa., president; H. W.

Conarro, general manager, Struthers Wells Company, Warren, vice-president; James P. Rogers, formerly general manager of the Rogers Shear Company, Warren, treasurer; H. R. McClure of the firm of McClure & Smith, Warren and Sunbury, Pa., secretary. The policy of the new company includes general enlargement of the facilities of the plant both in the manufacturing of new cars and in its repair department. One feature of the new company will be its leasing department, which it will conduct for the benefit of its patrons.

Joseph M. and James J. Flannery

Joseph M. Flannery and James J. Flannery, pioneers in the vanadium industry and the organizers of the Flannery Bolt Company and American Vanadium Company, died within three weeks of each other in Pittsburgh. Joseph M. Flannery was 52 years old. His death occurred on February 18, after an illness of seven months, while his brother died suddenly on March 6, at the age of 66, although he had been in poor health for over a year, but had been active in his business affairs up to the day of his death.

Joseph M. Flannery, who was also president of the Standard Chemical Company, was born in Pittsburgh. In 1904, with his brother, he began a tour of the world, seeking to discover a process whereby unbreakable bolts might be made. An analysis of the metal composing the fencing foils used in Sweden resulted in the discovery of vanadium. To the Flannery brothers is due the introduction of vanadium in the steel industry, marking an epoch in the advance of steel making. Convinced of the value of vanadium for this purpose, they obtained control of an enormous deposit of vanadium ore in the Andes of Peru, and successfully introduced its application in the manufacture of alloy steel, especially for automobile construction and certain locomotive parts, as frames, driving axles, connecting and piston rods. When the American Vanadium Company was sold a few months ago to the Vanadium Corporation of America, controlled by Charles M. Schwab and J. Leonard Replogle, it controlled about 90 per cent of the world's supply of vanadium. Joseph M. Flannery was also interested in the production of radium, and in 1911 organized the Standard Chemical Company, the world's largest producer of radium. At the time of his death he was also working to develop the commercial use of uranium in steel and other metals.

James J. Flannery was the executive head of the Flannery

Bolt Company, Pittsburgh, manufacturers of the Tate flexible staybolt, and was president of the American Vanadium Company. He was also interested in coal mining and was president of the Meadowlands Coal Company and the Montour & Lake Erie Coal Company.

The American Steam Conveyor Corporation, Chicago, announces that arrangements have been made with the Wellman Bibby Company, Ltd., 36 Kingsway, London, W. C., 2, England, to act as its representative in Great Britain and Ireland for the sale of the American steam ash conveyor. The Wellman Bibby Company intends to manufacture the American steam ash conveyor in England. This company is well known in the British Isles and handles the sale of a number of American engineering products there.

Automatic Straight Air Brake Company Starts Active Manufacturing

The Automatic Straight Air Brake Company announces that it has completed arrangements with Kidder, Peabody & Co., of New York and Boston, John F. Alvord, president of the Torrington Manufacturing Company and Hendee Manufacturing Company, and Geo. W. Goethals & Co., Inc., for the financing and manufacturing of its brakes. These three interests have purchased a controlling interest in the company and will immediately establish a plant for the manufacture of the brake.

John F. Alvord has been elected president. Harry I. Miller, who has been associated with the company from its inception, will be vice-president, in charge of sales. Harry B. Hunt, formerly of the engineering department of the American Locomotive Company and more recently a colonel in the Production Department of the Ordnance Bureau, has been elected vice-president and treasurer, in charge of manufacturing.

With the new organization the company will be prepared to enter upon the production of the automatic straight air brake on a large scale.

Spencer G. Neal, who is chief engineer of the company under its new organization, is the inventor of the automatic straight air brake and the man who has been in charge of its testing and development. He was born at Humboldt, Kan., in 1883. His family moved to southern California when he was two years old and he was educated in the public schools there. He entered railway service in 1898 and served as a machinist apprentice in the San Bernardino, Cal., shops of the Atchison, Topeka & Santa Fe. He then became a machinist and was for a time engaged in the installation of stationary machinery. Having then worked out the idea of the new brake, he spent from 1910 to 1912 on lines now part of the San Diego & Eastern, on which road the first tests of the brake were made. In 1913, he continued these tests on the Arizona Eastern, working out its development by means of passenger train tests between Globe, N. Mex., and Bowie, Ariz. He also continued these tests on a track at Los Angeles. He went to New York in 1914 and has had his headquarters in that city since, with the exception of time spent on tests of the air brake on the Atchison, Topeka & Santa Fe at La Junta, Colo., and on the Virginian.

VOLUME 94, NUMBER 5

New York—MAY, 1920—Chicago

ESTABLISHED IN 1832

Published Monthly by Simmons-Boardman Publishing Co., Woolworth Building, New York, N. Y. Subscription price, United States and Mexico, \$3.00; Canada, \$3.50 a year; foreign countries, \$4.00 a year. Entered as second-class matter, January 27, 1916, at the post office at New York, N. Y., under the Act of March 3, 1879.

Franklin Automatic Driving Box Wedge prevents the hammer blows that pound the running gear apart.

SMASH!

Did you hear that clanking, smashing noise when that engine went by?

It's the slack in the driving boxes and rod brasses.

The shoes and wedges are slack and the boxes and bushings are pounding out.

This begins in the driving boxes. It may be prevented by frequent adjustment of shoes and wedges, but sufficiently frequent adjustment by hand is impossible, simply for lack of time and men.

The Franklin Automatic Wedge does the adjusting mile by mile as the engine runs—and does it right.

In 1832 when the American Railroad Journal, the forerunner of the *Railway Mechanical Engineer*, was founded the subscription price was three dollars a year. In 1837 the journal was changed to a weekly and the price was increased to five dollars. Probably none of our readers remember when

The High Cost of Publishing

the change in the subscription price to two dollars went into effect. For many years this has remained unchanged; but recent increases in the cost of both labor and materials have been so great that the publishers are now forced to increase the subscription price to three dollars in the United States, east of the Mississippi and in Mexico and four dollars west of the Mississippi, in Canada and foreign countries. The increase in the subscription price beyond the Mississippi is due to discrimination against that section of the country embodied in an Act of the Congress which provides for geographical zone rates and progressive increases. The publishers regret this; but the action of the government leaves no alternative.

To some of our readers it may come as a surprise to learn that even the new subscription price will not pay the cost of the paper alone. The price of this one item has increased over 200 per cent and the end does not seem in sight. The increases in the cost of material and labor are matters which are probably of minor interest to our readers, however, and are mentioned only to avoid the charge of profiteering. The editors realize that the subscribers are most concerned with the way in which the publication covers its field. It will be our endeavor to make the *Railway Mechanical Engineer* worth all that it costs to our readers and the editors will welcome suggestions for improvement that will make it more valuable to railroad men.

In the past many railroads have been open to criticism because of their failure to accord to men in the minor supervisory positions either the compensation or the recognition to which they were entitled. The status of the foremen in the mechanical department has been improved during the past two years. It

The Importance of the Foreman

is to be hoped that conditions will continue to grow better and that a real incentive will be created so that the most competent and ambitious workers will be induced to strive for promotion and to make the most of their opportunities for further advancement. The lack of personal interest on the part of the higher officers is often responsible for a feeling of indifference among the foremen, which has a decidedly bad effect on the men under them. In this connection Dr. Hollis Godfrey recently said: "The one man most vitally affecting the workman is the foreman. When industry adopts education, when it teaches its management and its foremen to teach, it will eliminate many of the major causes of labor trouble. This will be done not merely through the development of the good fellowship that is inevitable. It will follow as a natural result of giving every man a real chance. When the foreman is taught by his industry and in turn becomes a teacher of the men under his orders, obstacles to each man's rise will be removed. Every man will have the same chance to progress. Nothing makes more difference in industrial unrest than the foreman; nothing can serve better to help industry and the workman than to make him a teacher."

Under present conditions the majority of general officers are burdened with a mass of detail which should be handled by their subordinates. The foremen, instead of being minor executives, are little more than clerks. This condition should not exist if the higher officers would accept Doctor Godfrey's

suggestion. Instead of throwing the foreman on his own resources, giving him little authority and expecting little of him, the roads should take steps to develop the foreman's executive ability, teach him how to handle men and outline the general policy which he should follow. With such training the foreman could be given more authority, more questions could be settled locally and the higher officers would be relieved of a large proportion of the detail work with which they are now burdened.

In an article on bronze and babbitt bearings appearing in this issue, the author, who is a manufacturer of bearings, has aptly referred to the scrap pile as the laboratory of experience and has commented on the lack of suitable bearing testing machines. If it is a fact that

Bronze and Babbitt Bearings

the value of such testing machines as we now have lies mainly in the testing of the lubricant, the design of a practical machine for testing the physical properties of journal bearings would appear to offer an excellent field for further development. The statement that the application of a single formula may result in a large variation in the structure of the bearings caused by different pouring temperatures or rates of cooling, and that consequently analysis is a faulty basis on which to purchase bearings, may lead to some discussion among our readers. It is also stated that conservation of tin during the war caused the United States Railroad Administration to specify high-lead bearings for the new cars purchased and as this resulted in an unusually soft bearing there is some question as to how soon these bearings will require replacement. Now that the cars to which these bearings were applied have been in operation some time it would be interesting to know what results are being obtained from these bearings in actual service.

Lack of material with which to complete repairs to equipment held in shops is perhaps the most frequent complaint heard from foremen and shop superintendents; it is also one of the best excuses ever offered for not getting the power out in time to suit the operating department. It would be difficult to

The Service of Supply

make a comparison between railroad and industrial shops without observing an unsatisfactory condition on the railroad, with respect to material supply, that cannot altogether be accounted for by the greater diversity of work encountered on the railroad. This view, however, does not take into consideration the fact that on any railroad the shops include many small units scattered over a wide territory as contrasted with industrial enterprises, which are generally concentrated within a single shop or group of buildings thus making it possible to provide at all times an adequate supply of material without accumulating an excessive stock. The shop foreman does not always appreciate just how expensive it is to maintain a stock of material that would be large enough to meet any possible requirement. In the eyes of the shop, every delay to important work on account of a shortage of material tends to overshadow any possible benefit obtained through carrying the smallest possible stock of all materials.

On the other hand it is possible for the stores department to overlook the loss that may be occasioned if material is not always on hand when it is needed. The general storekeeper or purchasing agent can usually carry his point with the management because he is able to produce a convincing statement showing the amount of money that can be saved by means of a reduction in material stocks, but it is next to impossible for the shop superintendent to prove in dollars and cents just what loss has been occasioned by equipment held in the shop waiting for material or to demonstrate what could actually

be saved through increasing certain quantities of material carried in stock.

This is a situation which admits of further study on the part of the railroads with a view to striking a proper balance between the objectives of the mechanical and the stores departments. A better mutual understanding of the problems of both departments with respect to the service of supply would be helpful.

For many years preceding the war the development of the locomotive may be said to have kept ahead of the times.

Overcoming Rising Costs

The war brought locomotive development practically to a standstill, while it increased the cost of everything entering into locomotive construction, maintenance and operation. The result is obvious. Locomotives are paying about one-half the dividends they did before the war; in other words, the cost of tractive effort has been doubled. These costs are not coming down and the railroad security holder will not be satisfied with a lower return. The efficiency of the locomotive must and will be increased to meet the situation.

For years the Germans applied feedwater heaters, while French and English locomotives were somewhat of a curiosity to us because of their light reciprocating parts. More recently pulverized coal has been used on Brazilian locomotives. In pre-war years the American locomotive development was so rapid that the railroads were satisfied to "let well enough alone" and ignored the refinements introduced abroad because costs, particularly fuel cost, were so much lower in this country. Now that cheap coal is a thing of the past there can be no argument against the feedwater heater, lighter reciprocating parts and the use of inferior coals in pulverized form.

Will the railroads utilize the 15 to 20 per cent saving resulting from the use of a feedwater heater and take advantage of alloy steels, not only to reduce dynamic augment but to lighten the weight of reciprocating parts so that boiler capacity can be increased? Will they take the initiative in the development of the use of pulverized coal as a means of utilizing anthracite culm and Dakota lignite? Or will the railroads continue to view these developments from a critical standpoint? It is easy to say that the feedwater heater will add to maintenance, that alloy steels increase the first cost of the locomotive and that pulverized coal is entirely a development for the future, but it is imperative that mechanical men make these developments a success rather than an obstruction. The motive power department has a better opportunity today than ever before to improve locomotive efficiency.

In large modern locomotives the boiler often extends up nearly to the limit of the road clearance and the height of the steam dome is greatly restricted.

Wet Steam Decreases Efficiency

This in turn necessitates placing the throttle valve relatively close to the normal water level in the boiler, and as a result there is a tendency for water to be entrained in the steam at high rates of evaporation or when the water is carried too high. This carrying over of water takes place even with the best water supply and is of course aggravated when the water carries impurities that cause foaming or priming. Tests made under both laboratory and road conditions have shown that the steam entering the dry pipe may have as high as four to six per cent of moisture.

If moisture is carried over with the steam the superheater must evaporate the entrained moisture and the superheat is therefore reduced. The amount of heat required to evaporate water is relatively high when compared with the heat

needed to superheat steam; therefore even a small percentage of moisture will cause a serious reduction in the superheat. To convert one pound of water at 200 lb. pressure into steam requires 838 B.t.u., but only 60 B.t.u. are needed to superheat the steam 100 deg. F. Therefore, an increase of five per cent in the moisture content will cause a decrease of 70 deg. in the superheat, assuming that the rate of heat transfer through the tubes is unchanged. If evaporation takes place in the superheater to any considerable extent the unit tubes become lined with scale, thus reducing the rate of heat transfer and cutting down the superheat under all conditions. The serious results of a high moisture content in the steam can be realized from the fact that a falling off in the superheat from 250 deg. to 180 deg. (equivalent to an increase of five per cent in the moisture in the steam) raises the coal consumed about 15 per cent. In other words, each increase of one per cent in the moisture content of the steam will cause a three per cent increase in the fuel consumption.

The loss of efficiency resulting from the entraining of moisture is so serious that the problem of overcoming this trouble deserves careful study. If the dome does not extend up to the clearance limits, the quality of the steam may be improved by making it higher and raising the inlet to the throttle. Locating the dome some distance ahead of the rear tube sheet should be an advantage as the ebullition is least rapid over the forward part of the tubes. Throttle valves which draw steam only from the extreme upper part of the stand pipe are also advantageous. If with the best arrangement of dome and throttle that can be devised the moisture content of the steam is still high, a steam separator may be needed. Plans are now under way for the installation of a steam separator and its effect on the quality of steam will be watched with interest. The fact that an increase of one per cent moisture in the steam will cause an increase of three per cent in fuel consumption is of sufficient importance to warrant the most serious consideration of this problem.

NEW BOOKS

The Condensed Chemical Dictionary. 523 pages, 6 in. by 9 in., bound in cloth. Published by the Chemical Catalog Company, 1 Madison avenue, New York.

In the shipment of chemical products, railroads are often confronted with the perplexing problem of determining whether the nature of the chemical makes its transportation hazardous. Realizing the need for a work that would give in a condensed non-technical form information regarding the properties of chemicals, the publishers have compiled this reference work. In addition to a concise statement of the physical and chemical properties commonly included in more

voluminous works, there is stated for each substance the type of container used, the fire hazard and the railroad shipping regulations. While the book will be found particularly useful for those who desire data in a non-technical form, it should also prove a handy reference work for chemists.

Mechanical World Year Book for 1920. 328 pages, 4 in. by 6 in., illustrated, bound in cloth. Published by Emmott & Co., Ltd., 65 King street, Manchester, England.

This is the latest edition of an English reference book that has been in publication for 33 years. The current edition is an enlargement over previous issues and contains several new features, including an important section dealing with water and hydraulic work in which information is given on the friction of water in pipes and on pumps and pump fittings. The applications of hydraulic power are described and data given on hydraulic accumulators, hydraulic press cylinders, flanging presses, punching presses, hydraulic pipes and flanges. Another addition is a section on heating and evaporating liquids. This includes descriptions of tubular heaters, feedwater heaters and evaporators. The book is quite complete with respect to gas and oil engines, particularly the Diesel engines.

Inventions, Their Purchase and Sale. By William E. Baff. 230 pages, 5 in. by 7½ in., bound in cloth. Published by D. Van Nostrand, New York.

This book is written by a patent attorney who is familiar with the steps by which many inventors have turned their patents to good account and contains many commonsense suggestions on how to make the most out of an invention after the patent has been obtained. It is essentially a business man's book on the marketing of inventions and does not deal directly with inventions in their inception and handling through the patent office, but rather with the methods of obtaining the greatest return

Invention has played an important part in railroad development and patents developed in railway practice are usually taken in hand by some carrier for the privilege of using the device if it proves successful in operation. If the inventor obtains a broad patent upon a meritorious device he is usually successful in placing it in the hands of an established supply house and does not find it necessary to engage in the business of marketing his invention in order to realize a profit from it. However, no inventor can afford to overlook the business viewpoint. No matter how ingenious his invention may be, it must be something upon which business men can make a profit. This book will recommend itself to any inventor who is anxious to know what is required of a patent to make it successful from a commercial as well as a mechanical standpoint.

What Do You Think?

In what way do you believe that locomotive efficiency and capacity can be most effectively increased? In this issue Mr. Milner has suggested three or four ways in which he thinks this can be done. If you don't agree with him or can suggest a better means, the *Railway Mechanical Engineer* would like to know your views.

The article on new electric passenger locomotives for the St. Paul indicates very clearly that electrical engineers have not come to any agreement on the best type for passenger service on mountain grades. If you are keeping in touch with electrical matters, as you should, you may be able to give us your own idea as to the best type.

Determining the proper loads for locomotives is a live topic. Mr. Mounce's article will add something to your knowledge of this subject, and if you have a theory on train loading, now is the time to put it into an article.

Freight car repair methods vary the country over. This issue describes in a very complete article how the work is done on the E. P. & S. W. If you cannot tell us how you are repairing cars on your railroad, perhaps you can send the *Railway Mechanical Engineer* some good pictures and a few notes that will tell the story.

In the Shop Practice Section the article on measurement records outlines a method that might be useful in your shop. What do you think about it?

The New Devices Section should not be overlooked if you want to keep up to date.

The *Railway Mechanical Engineer* solicits cooperation on the part of its readers; don't be satisfied with subscribing but contribute something.

COMMUNICATIONS

ABUSE OF SAFETY APPLIANCES

CINCINNATI, OHIO.

TO THE EDITOR:

There has been a great deal said and written about the inspection and maintenance of safety appliances, but there is very little said about the abuse of them. This abuse is principally due to rough handling or carelessness on the part of trainmen. It is a common occurrence to find several cars on repair tracks daily with ends broken out, causing loose side and end grab irons, or bent and inoperative brake staffs, or uncoupling levers.

Often couplers are pulled out of cars, which are then switched from one track to another, damaging the safety appliances on every car they come in contact with, which could be avoided if the cars were properly disposed of after being damaged.

Safety appliances were made for the protection of trainmen, but as a rule they receive very little consideration, as these employees apparently have little respect for safety appliances or any other part of a freight car.

E. F. C.

THE MECHANICS' VIEWPOINT

MEADVILLE, PA.

TO THE EDITOR:

A workman is a funny animal, and to handle him requires tact, diplomacy and a working knowledge of human nature; like a mule he can be led but not driven, and a little appreciation goes a long way to help the monotony of his daily grind, for such it gets to be. Never lose sight of the fact that a man is attracted to the particular work he chooses more by inclination than by circumstances. He follows a bent, a leaning. The way to get the best from him is to *keep him interested*.

This can be done in various ways — by showing a little interest in him and his work, by indirect suggestion, by creating a little friendly rivalry, by an efficient first-aid chest, by fair compensation and by real appreciation. Some men handle their workmen on the theory that they will be impressed and produce more if they, the big men, keep away—hold themselves aloof. Get acquainted with your men, place them to the best advantage, take a healthy interest in their work and the little troubles they have with their jobs and machines, and you will get results.

The last hundred years have shown more advancement than all the years gone before. To be up to date requires more application and study as the times progress; the day of the all-around man has given way to the specialist. The field has broadened to such an extent that he who covers it all knows very little of any one thing, and is constantly running afoul of unseen situations that are easy to foresee and be met by the one on the ground, so to speak. Knowledge commands respect in the shop as in other walks of life, and is a result-getter—one of the best, one that will endure.

You would be surprised if I told you I never saw a man on any kind of a job that was not pleased at the prospect of increased production through the medium of better tools, improved methods, or short cuts. It is a fact, and instead of holding down the output, as he is sometimes accused, he really hopes in some way, not always clear to him perhaps, to increase his daily average; when he does, a little hearty interest repays him and spurs him to greater efforts.

One of the hardest things for man today is to be broad-minded, to look without prejudice at the two sides of a question. Some reasons that make it harder are knowledge of

only one side of the question, not being interested in two sides, dwelling on theories at the expense of the practical, aloofness and selfishness.

When the big man comes late to work fresh from his daily bath, things naturally look different to him. He goes about his side of it left handed; his comfortable ideas of his own greatness make it hard for him to come down to common everyday problems and explains the breach between him and his men. If the average big man was to obtain the private opinion of his men he would be surprised; he would find the workman's ability to absorb punishment had in no way dulled his sensibilities and the high standard of living of the American worker puts him in a class alone; he must be considered and handled differently than alien labor.

Never advocate piecework as it is the surest way to get indifferent quality and, of course, larger quantity, as quantity is all the pieceworker can see; it is hard on the nerves of the nation and in due time will show its effects. There are other ways to get results, and the dawn is open for them.

FROM A RAILROAD MECHANIC.

[This letter was not written for publication, but is taken from a personal letter to one of the members of our staff. It is so much to the point that we felt it would be of interest and help to many of our readers in directing the efforts of the men under them.—Editor.]

LUBRICATION OF CYLINDERS

CHICAGO, ILL.

TO THE EDITOR:

In your editorial on "Lubrication of Cylinders," in the March issue, you call attention to the various points at which the oil is injected, but say nothing about the manner of delivery. It stands to reason that with the gravity lubricator, the lower the point at which the oil is injected into the steam the more regular the delivery will be. Connecting the gravity feed lubricator pipe to the cylinder instead of in the steam pipe has the additional advantage of delivering the oil into steam of less pressure. These two factors, the greater pressure head and the reduced resistance pressure, should tend toward an improved cylinder lubrication, provided carbon incrustation can be avoided.

I cannot, however, see how the valve lubrication would be improved, since it is conceded by those who advocate gravity lubricators feeding into the cylinder only, that the live steam valve rings would have to depend for lubrication on the oil that is carried by the exhaust rings of the valve to that part of the valve chamber wall traveled by the live steam rings.

You also state that there is a growing tendency to dispense with swabs on piston rods. The reason you give, however, is not the whole cause. The principal reason is that the rod packing cannot pack against a thin film of oil so that with pressure inside the cylinder and no pressure outside, enough oil impregnated steam leaks by the packing to lubricate the rod.

If the above holds true we should not expect good lubrication of the live steam valve rings, because the conditions are just the reverse of rod lubrication. In the rod lubrication the pressure side carries the oil to the non-pressure side, which is natural, while with the valve lubrication we should not expect the lower exhaust pressure side to carry and maintain the oil in the higher live steam pressure side.

It seems reasonable, therefore, to lubricate the live steam side of the valve first, by injecting the oil into the steam pipe about 20 in. above the valve, and with the same oil impregnated steam, lubricate the cylinder and, again, as an extra precaution that does not cost anything, use that same oil impregnated steam to lubricate the exhaust side of the valve. It is absolutely necessary, to realize the best results from the scheme above outlined, to inject the oil into the steam at every revolution of the drivers, as can be done with a force feed lubricator.

W. J. SCHLACKS.

St. Paul Passenger with General Electric Locomotive

NEW ELECTRIC LOCOMOTIVES FOR THE C. M. & ST. P

Description of Two Radically Different Types Recently Designed for Passenger Service

FIFTEEN additional electric passenger locomotives are now being constructed for the electrified divisions of the Chicago, Milwaukee & St. Paul. Five of these are being built by the General Electric Company and ten by the Westinghouse Electric & Manufacturing Company in conjunction with the Baldwin Locomotive Works.

The motive power equipment for the initial electrified division of 440 miles over the Rocky Mountains consisted of 32 freight locomotives, 10 passenger locomotives and 4 switching locomotives. When it was decided to electrify the division over the Cascade Mountains these 15 new passenger locomotives were ordered. The original 10 passenger locomotives will be regeared for freight service, so that the St. Paul will now have 15 passenger, 42 freight and 4 switchers, or a total of 61 electric locomotives in service on the two electrified divisions.

The two new types of electric passenger locomotives built for the Chicago, Milwaukee & St. Paul were designed for the same class of service by different groups of engineers working independently; from an inspection of the finished locomotives it would appear that the two types could hardly be more different.

Roughly the requirements for both designs were as follows: The locomotives must collect 3,000 volt direct current power from an overhead catenary. They must be able to haul a 12-car passenger train weighing 950 tons over a two per cent grade, compensated for a distance of 20 miles, and over a 2.2 per cent grade compensated for a distance of 17.8 miles. They must maintain speeds of approximately 25 miles an hour up two per cent grades, 35 miles an hour up one per cent grades, 60 miles an hour on level tangent track and must hold trains on down grades by regenerative braking at speeds consistent with safe operation. The sharpest curve on the main line is 10 deg., but the specifications required that the loco-

motives must negotiate a 16-deg. curve in the yards satisfactorily.

The General Electric Locomotive

The running gear of the General Electric locomotive is composed of four individual trucks, two end trucks having three axles each, and two center trucks having four axles each. These trucks are connected together by special articulation joints. The motor armatures are mounted on the axles and the motor fields are carried on the truck frames.

The two end sections are similar to each other in appearance. The operator's cab in either section is on the inner end next to the heater cab above described, in order that the operator can be convenient to the heater and in order to allow a maximum space for apparatus in the apparatus cab or outer end section. Another advantage of this arrangement of cabs is that the operator can have access to any section of the locomotive requiring his presence without passing through a section containing high-tension apparatus. The engineer's or operating cab contains a main or master controller, the air brake valves and handles, and an instrument panel, containing air gages, ammeters, and speed indicator. The engineer uses either of the two operating cabs according to the direction in which he is running.

A door gives access from the operating cab to the apparatus section which extends with a cylindrical top to the extreme end of the locomotive. The cylindrical construction naturally adapts itself to the protection of the apparatus included and in addition to this it has the advantage of allowing a clear vision for the operator from his normal operating position.

Motors

The motors are of the bi-polar gearless design which were adopted by the New York Central 14 years ago for operating

heavy passenger trains between Grand Central Station and Harmon, N. Y. To insure light weight per axle, flexibility in control, good truck arrangement for curving as well as for high-speed running, twelve motors are chosen, each of relatively small capacity. They are especially designed to withstand high temperature, being insulated with mica and asbestos. The continuous rating of each motor at 1,000 volts and with 120 deg. rise by resistance is 266 hp., corresponding to 3,500 tractive effort at the rim of the drivers at a speed of 28.4 mi. per hr. Forced ventilation is employed for cooling. The armature core is provided with holes for the passage of ventilating air. Ventilating blowers are located above each motor armature and deliver air at the commutator end of the motor where it divides, a part passing through the armature and a part back through and around the field coils where it escapes upwards and is afterwards used for ventilating the starting resistors.

This type of motor lends itself nicely to simple and compact locomotive design as the frame is made use of to furnish the entire path for the magnetic flux. The pole pieces

in series across 3,000 volts. The second combination has six rheostatic steps, one full field step, and one tapped field step, with six motors in series and two sets in multiple. The third combination has eight rheostatic steps, one full field step, and one tapped field step, with four motors in series, and three sets in multiple. The fourth combination has eight rheostatic steps, one full field step, and one tapped field step, with three motors in series, and four sets in multiple. This results in a total of 39 control steps with a choice of eight operating speeds, exclusive of the resistance steps.

The regeneration of power for braking is accomplished by using some of the motors for exciting the fields of the others, which in turn are used as generators to return power to the line.

Auxiliary Apparatus

The center cab is occupied by an oil-fired steam boiler for heating passenger trains and with accessories, including tanks for oil and water, circulating pumps, and a motor-driven blower for furnishing forced draft. This center portion of

Profile Showing the Two Electrified Divisions of the Chicago, Milwaukee & St. Paul

and field coils are fastened to the cross transoms of the trucks and the magnetic flux passes horizontally in series through all twelve motors, finding a return path through the locomotive frame. The articulation joints between the trucks are made in such a manner that large surfaces are in contact to provide an easy path for the flux. The pole pieces are made flat in order to prevent the pole pieces from coming in contact with the armature during the vertical movement of the truck frame on its springs or when removing or assembling the armatures. A minimum clearance of 1/8-in. on each side is allowed between the armature and the pole piece tips. The brushholders are bolted to the transom allowing the brushes to move up and down with the fields as the frame rides on the truck springs.

Control

The control for motoring is arranged for four motor combinations. The first combination has nine rheostatic steps, one full field step, and one tapped field step, with twelve motors

the cab may be lifted out in case the steam boiler is in need of heavy repairs.

Power for train lighting is obtained from the motor-generator set. A switchboard located in the operator's section of one of the cabs is equipped with switches, resistors and meters for controlling the train lighting circuit. The head end system of lighting is in use on the trains over this division. In the other operating cab is a small motor-driven air compressor, operated from the battery circuit, with sufficient capacity for raising the pantograph when first putting the locomotive in operation.

A slider pantograph, similar in construction to those now in use, is mounted on each of the operating cabs. This pantograph has two sliding contacts, giving a total of four on the slider with a double trolley. The pantograph and flexible twin trolley construction enable the locomotive to collect current as high as 2,000 amperes at speeds up to 60 miles an hour without noticeable arcing at the contact points. The second pantograph is held in reserve as a spare. Sand boxes,

with pipes leading to each pair of driving wheels, are located directly beneath the pantographs outside of the operating cab.

Mechanical Construction

To soften any lateral blow that may be given against the rail head, the leading and trailing axles are allowed a movement of one-half inch relative to the truck frame, either way from their central position. This movement takes place against a resistance introduced by wedges above the journal boxes which tend to hold the box in its central position and to give a dead beat action opposing the motion. To further protect the track from lateral displacement on the ties, the outer end of the superstructure is carried on rollers, bearing on inclined planes upon the truck frames, while the inner end of the superstructure is rigidly bolted to one of the middle trucks. This construction tends to hold the leading and trailing trucks in their central position.

View from Engineer's Position on General Electric Locomotive

When a blow is delivered by the leading or trailing truck against the rail head, the superstructure, which is rigidly bolted to the middle truck, is displaced laterally across the outer truck very much as a boiler of a Mallet locomotive swings across its leading truck. In such a sideways displacement, the weight of the superstructure rolls up on the inclined plane on that side and thus transfers weight to the rail that is affected, thereby increasing the adhesion of the rail to the tie. This action really has two results. It not only increases the holding power between rail and tie at that point, but it introduces a time lag and increases the time and distance during which the pressure is delivered to the rail head.

The Baldwin-Westinghouse Locomotive

The locomotive consists of two duplicate running gears of the Pacific type, placed back to back, supporting a single cab. The wheel arrangement of the locomotive is 4-6-2-2-6-4, with 68-in. drivers, a rigid wheel base of 16 ft. 9 in. and a total wheel base of 79 ft. 10 in. Rigid and floating center pins have been provided to relieve the cab structure of pulling and bumping strains, all such forces being transmitted directly through the running gear.

The articulation of the various trucks was considered one

of the most important points of design. It was the endeavor to have each truck laid down so that each one would take care of itself and would not have to be led along by any of its companion trucks. During a series of tests made at East Pittsburgh, Pa., this feature of the mechanical operation of the locomotive was pronounced and the locomotive was declared to have especially good riding qualities. An extensive study was also made of weight distribution and its equalization between trucks. With this latter end in view, comparatively long spring hangers have been used so that any slight increase or decrease in their length for the purpose of shifting the load does not have any noticeable effect on the position of the locomotive springs.

Motors

The 3,000-volt direct current power is conducted through the necessary switches and resistances to six motors of the

Cross Section of Journal Box, Showing Wedges Used to Give Resistance to Lateral Movement on General Electric Locomotive

twin-armature type mounted on the locomotive running gear. The two armatures of each motor are permanently connected in series, and the control is so arranged that at least two motors are always in series, with the result that the voltage across any one armature never exceeds the value of 750 volts during motor operation. In addition to this, the control is further arranged so that all main motor fields are connected on the grounded side of the circuit, thus maintaining most of the voltage stresses on the motors practically in line with commercial usage for the past 15 or 20 years.

One motor is mounted over each driving axle on the frame of the locomotive, and power from each armature is transmitted by pinions to a gear with an 89:24 reduction. The gear is mounted on a quill shaft, which is also supported on the locomotive frame, and which surrounds the locomotive axle with an appreciable clearance. The connection between the driving wheel and the quill shaft is made by springs. One end of each spring is connected to the quill shaft, while the other engages a bracket on the spoke of the driving wheel.

This arrangement permits the driving wheels to follow the unevenness of the roadbed, without affecting gear mesh, as well as cushioning the torque of the motor. In the design of this type of quill shaft the details have been governed by the experience obtained from the successful application of a similar type of drive on the New York, New Haven & Hartford locomotives, making due allowance for the increase in tractive effort.

The manner of regenerating power for operation on down grades used on these locomotives embodies features which have not been used before. The main driving motors are series motors, and in order to make them regenerate power to the line it is necessary that they be separately excited. The control of the excitation of the main motors for regeneration is initiated manually by the operator from the master controller, the exciting current coming from two small generators geared to one of the axles of each bogie truck. These small generators in turn are excited from an independent source, consisting of a motor-generator set operating in parallel with a small storage battery. All of the main motors are used during regeneration. Efforts have been made in the design of main motors and the axle generators to guard against any possibility of snow getting into the windings. One of the axle generators is mounted on each bogie truck in a standard street railway motor frame.

Control

The locomotive control provides three motor combinations, giving one full series and two series-parallel connections.

set and storage battery which are used to excite the fields of the axle generators. The high-tension winding of this set is the only piece of revolving apparatus in a locomotive, with the exception of the main motors, which is connected to the 3,000-volt circuit. The low-tension side of the motor generator set is provided with slip rings for the generation of a low voltage alternating current for the headlight and for some of the interior cab lights. During motoring and when coasting without regeneration, the axle generators are automatically connected to the low voltage auxiliary circuit, so that the motor generator for the greater part of the time is only necessary for furnishing excitation to the axle generator field and for charging the storage battery. This reduces the necessary size of the motor generator set.

The center compartment of the locomotive is given up entirely to an oil-fired steam boiler, its supply tank and auxiliaries. This boiler supplies steam for heating trains and is capable of evaporating 4,000 lb. of water per hour. Two storage tanks for water are provided, having a combined capacity of 25,500 lb. of water. There is also a tank for the fuel oil, with a capacity of 750 gallons. The boiler

Running Gear of One Half of the Baldwin-Westinghouse Locomotive With Motors in Place

The two latter connections consist of two parallel circuits of three motors in series and three parallel circuits with four motors in series. In each of these motor combinations three running notches are provided, which are full field, short shunt and long shunt. This provides a total of nine running speeds without resistance connected in the circuits.

While descending a grade the excitation of the motor field is entirely under the control of the engineman and may be increased or decreased as desired, causing corresponding increments and decrements to the regenerative effort of the locomotive, thus varying the speed of the train through any desired range. The full motor capacity of the locomotive is available for regeneration, and under all conditions of grade on which it will be used it should be able to handle any train down grade that would require double-heading on the way up.

Auxiliary Apparatus

Power for energizing the control circuit and operating the auxiliary apparatus, a small blower motor, the motor-driven air compressor, etc., when these are not being driven by the axle generator, is obtained from a small motor generator

also feeds radiators located in each of the operating cabs.

Comparative Data for the Two Locomotives

	General Electric	Westinghouse	
Total weight	521,200 lb.	550,000 lb.

INCREASING LOCOMOTIVE EFFICIENCY AND CAPACITY*

Improvements Suggested Include Feedwater Heating, Trailer Booster, Lighter Rods and Cut-off Regulation

By B. B. MILNER

Engineer of Motive Power and Rolling Stock, New York Central

IN discussing methods of increasing the efficiency and operating capacity of steam locomotives, I shall pass over the well worked questions of maintenance, fuel, feedwater, feedwater treatment, lubrication, stokers and the whole unlimited question of locomotive design by confining my remarks to a very few operating efficiency and capacity increasing adjuncts which I believe important because susceptible of profitable application to existing power.

Feedwater Heaters

First, I shall suggest one locomotive accessory, which in my judgment stands out with surpassing and immediate importance, viz.: the feedwater heater, an instrument by means of which a portion of the heat ordinarily rejected at the stack of a locomotive may be conserved and used by abstracting this heat from either the smokebox gases or the exhaust steam, and using it for the preheating of feedwater. Thus far the heat source of the more successful schemes for thus conserving the ordinarily rejected energy has been the exhaust steam. These schemes involve replacement of the injector. The injector is a 100 per cent instrument from the standpoint of returning to the boiler all of the heat energy delivered to it from the boiler in the form of operating or driving steam, and it does most efficiently take feedwater at ordinary temperatures and deliver it to the boiler. The energy of the steam supply is divided between elevating the feedwater temperature and imparting to it the kinetic energy necessary to drive it into the boiler, and there is practically no heat lost. Against this arrangement, a saving must be represented in elevating the temperature of the feedwater by the use, not of heat drawn from the boiler, but of heat otherwise rejected at the stack, provided, of course, that the energy consumed by the mechanical operation of the feedwater heating means does not approach closely the quantity of heat caught and used instead of being rejected. A number of such means are now currently and regularly raising the ordinary temperature of locomotive feedwater—say, from 62 deg. F. to approximately 212 deg. F., or through a range of 150 deg. F.

Twenty or more years ago, the late M. N. Forney introduced a paper on the feedwater heater with the following statement: "To convert one pound of water of zero temperature into steam of 200 lb. pressure requires 1231.7 units of heat; a unit being the amount required to raise one pound of water one degree. If the average temperature of water in a locomotive tender is 60 deg., then $1231.7 - 60 = 1171.7$ units of heat must be imparted to it to convert it into steam of the pressure named. One per cent of that will be 11.71 units, so that if each pound of feedwater is increased that many—or say 12 deg. in temperature, by waste heat, before it enters the boiler, it will be equivalent to a saving of one per cent of the fuel required to convert it into steam. This is true theoretically and has often been proved practically." Therefore, a locomotive feedwater heater which raises the temperature of feedwater through 150 deg. F., gives a fuel saving of over 12 per cent—a considerable margin of saving upon which to work.

It therefore appears that the problem of successful feedwater heating by means of exhaust steam should not involve any elaborate tests, particularly directed to the ever

difficult weight and work measurement of fuel economy, but may and should be properly restricted to the mechanical performance of the feedwater heating instrument, the reduction in the cost of its maintenance and the development of assured continuity of service. We are dealing with such a large actual economy that the carriers may well afford the expenditures involved in the contribution to more definitely establishing the solution of the mechanical problem involved, without any particular concern for the question of what may be the thermal results upon which actual savings in fuel consumption must necessarily be based; that is, they may well afford active contribution to the working out of whatever mechanical difficulties may yet have to be met by the application and use of feedwater heater equipment now available or hereafter developed for locomotive service.

The above has been addressed particularly to the question of efficiency or economy. The question of capacity is also favorably affected in that not only is heat reclaimed from the exhaust and used, but the condensed steam as well. And to the extent that condensation is so reclaimed, it is returned to the boiler, thereby reducing the quantity of water which must be supplied to the locomotive tender for covering a given amount of work. The quantity of steam reclaimed from the exhaust figures about 15 per cent. This means that a locomotive tender of given capacity will cover an amount of work that much greater; that either the work per unit of time may be correspondingly increased or, if this work remains constant, it may be continued for a correspondingly greater distance or time. Every pound of steam reclaimed from the exhaust reduces by that amount the weight of tank water which must be evaporated.

Trailer Booster

There has been recently developed what has come to be known as a "booster," consisting of an ordinary reciprocating steam engine geared to the locomotive trailer wheels, designed for use as may be required in the starting of trains, getting them to speed the more promptly, or both, by adding to the tractive efforts ordinarily developed at the lower speeds.

The operation of this booster is controlled by air pressure. At the front end of the reverse lever quadrant is provided a manually operated latch, by means of which the booster is made "normally" inoperative or operative when the reverse lever is in the extreme forward position. With this latch in the operative position, the reverse lever, when pushed "into the corner" engages an air valve which permits air pressure to pass from the main reservoir to the booster clutch cylinder, and thence to what has come to be known as the pilot valve, mounted back of the boiler dome. When the main throttle is opened, a supply of steam from the dry pipe to this pilot valve causes it to permit air pressure from the booster clutch cylinder to open the booster throttle valve. When the reverse lever is pulled "from the corner" or the latch at the front end of the reverse lever quadrant is "thrown out," the booster's steam supply is cut off and the booster clutch immediately disengaged. The apparatus is, therefore, protected against damage from broken pipes, lack of air, or damage from other possible cause. When the booster is not in use, it is "out of gear" and idle, none of its parts being in operation, and the performance of the locomotive then being in no way affected by reason of the booster application. Characteristic drawbar-pull and horsepower-speed curves

*From a paper presented before the New York Railroad Club, April 16, 1920.

taken from dynamometer car data are shown by Fig. 1, from which it will be noted that the initial drawbar-pull is, by use of the booster, increased from some 37,000 lb. to 47,000 lb., that the increase in drawbar-pull and the horsepower begins to diminish perceptibly at about 15 miles per hour, and that the booster becomes a load upon the regular locomotive cylinders at speeds approximating 20 miles an hour. Recalling, however, that the booster operation is discontinued by removal of the reverse lever "from the corner," it will be understood that interruption of booster operation is assured for quite some time before having attained even the speed of 15 miles per hour, at which the advantage in the use of the booster begins to appreciably diminish; that is, long before the diminution of this advantage occurs, and much longer before there is any possibility of the booster becoming a load on the main cylinders, the booster will always have been thrown out of gear. Fig. 1 also discloses the wide margin in the ability of the boiler to supply the booster with steam, as has been proven in service, and becomes very apparent by realization of how small are the horsepower outputs from the start up to speeds at which the booster will be thrown out of gear, in comparison with the much larger horsepowers for which locomotive boilers are all amply able to supply the necessary steam.

The booster, as a means of helping existing locomotives

Fig. 1—Drawbar Pull and Horsepower, With and Without Trailer Booster

through work which they are now only able to do with difficulty, if indeed they are able to do at all, will result in the satisfactory handling of larger trains, increased acceleration rates, or both. Increased acceleration should be particularly valuable in frequent-stop passenger service, and the higher initial or starting drawbar pulls and the ability to start heavier trains should be valuable in both freight and passenger services under what are now trying, if not prohibitive, starting conditions. The booster is applicable to most existing trailing wheel locomotives, and should materially increase the efficiency of operation, particularly from the standpoint of the locomotive being a transportation producing instrument.

The curves in Fig. 2, however, show clearly the advantages of the booster use from an acceleration standpoint, the train hauled being one consisting of 2,210 gross tons in 104 cars on a slightly opposing grade. Note, for example, that without the booster the speed of 16 miles an hour was obtained in 450 seconds, while with the booster this speed was obtained in 250 seconds or in nearly 50 per cent less time, amounting to over three minutes. The arrangement will undoubtedly prove a valuable addition to many existing trail-

ing wheel locomotives which have become inadequate to serve needs on account of deficiency in starting capacity, and also valuable for new trailing wheel locomotives in that greater starting power and capacity may be obtained without increasing the boiler, number of driving wheels, or materially increasing weights.

Dynamic Augment

Another way to increase the operating capacity of locomotives is to lighten the reciprocating and revolving weights by the use of alloy steel. This will permit of increasing the

Fig. 2—Curves Showing Increased Acceleration Secured With Booster

weight of the boiler without increasing the rail pressure at speeds. In fact, the rail pressure at speeds may be actually reduced with even heavier boilers by reducing the dynamic augment of the balancing forces. This subject is sufficient for a paper by itself and may be only mentioned here.

Proper Cut-off for Maximum Horse-Power

One of the most important factors in locomotive operation and one to which very little attention has been paid, is the science involved in selecting the proper cut-off or the reverse

Fig. 3—Composite Drawbar Pull—Speed Curve

lever locations required at various speeds for the development of maximum horsepower or drawbar-pull. Everyone probably knows that for any and each particular speed, there is only one reverse lever position or cut-off at which the locomotive will deliver its maximum in either horse-power or drawbar-pull; that is, if this reverse lever position be notch 07, cut-off 78 per cent, at say, 14 miles per hour, in any other reverse lever position and at any other cut-off, either greater or less, the locomotive will not deliver the maximum at this speed. But how do enginemen actually select vari-

ous reverse lever positions at various speeds, or how have they been taught to select them when maximum horsepower or drawbar-pull output is desired or actually required in order to go through a "tight" situation either on account of the liability of "sticking" or of failing to make satisfactory time. I suggest that to have done so little for engineers in this connection is, to say the least, somewhat of a reflection. To spend time and money in the arrangement and design of a locomotive, which in these days represents an investment of \$60,000 or more, and then turn such an engine over to engineers to run "catch as catch can," so far as concerns cut-off selection, is not very creditable.

The graphic chart, Fig. 3, shows the general relations existing between speeds and the drawbar-pulls developed by the use of the various constant cut-offs as represented by reverse lever notches, numbered 1, 4, 7, 10, etc., consecutively from the most forward or longest cut-off reverse lever

maximum drawbar-pull, must obtain and be used if maximum results are to be secured. What I have said covers the situation in a general way, but there remains the problem of how the necessary cut-off-speed-drawbar-pull data may best be obtained, and having obtained it how use may be made thereof. By inserting a second speed controlling engine between the dynamometer car and the train the drawbar-pulls developed by the first or leading engine ahead of the dynamometer car and under test, may be very easily obtained for all desired speeds. In Fig. 4 are shown the results of four tests made with the same engine and same train on the same day over a ruling grade indicating the advantage of using proper cut-offs.

All of the information, supplemented only by a watch, used in making the fourth and successful run covered by Fig. 4, is shown by Fig. 5, which presents the front and back of conveniently arranged vest pocket cards for the use

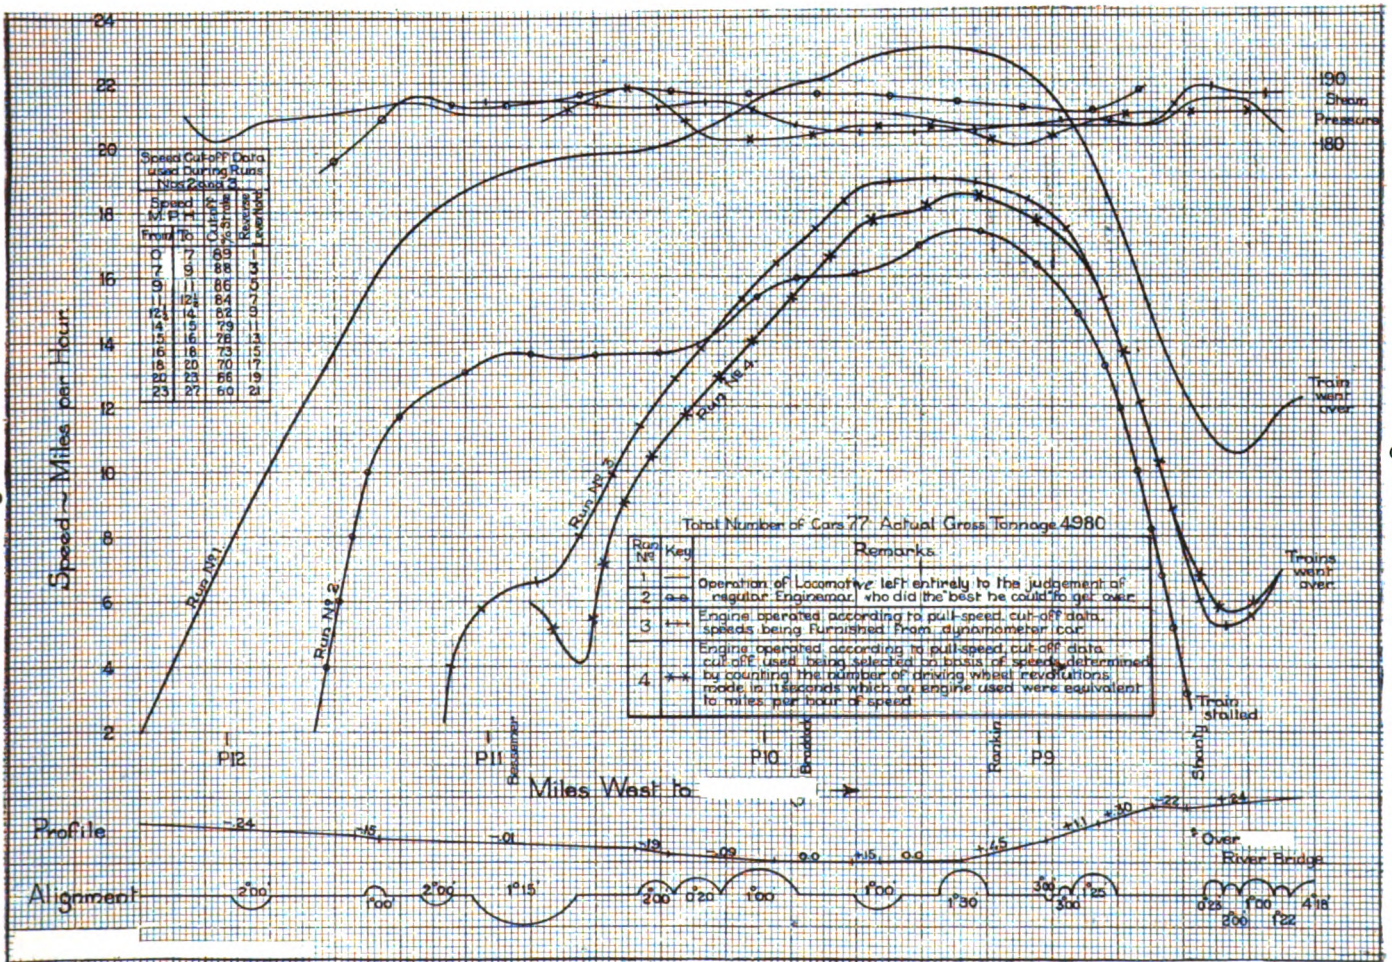

Fig. 4—Graphic Chart of Four Runs, Indicating the Advantage of Using Proper Cut-Off

position. In accordance with facts, this chart indicates that initial drawbar-pull at zero speed, or when starting, decreases with decreases in the cut-off used; that is, a longer cut-off will develop a higher initial drawbar-pull, whereas a shorter cut-off will develop a correspondingly lower initial drawbar-pull. This chart also indicates that at successively higher speeds, successively shorter cut-offs develop maximum drawbar-pulls, or in other words, for any speed there exists a definite cut-off at which the drawbar-pulls will be maximum and the selection of any other than the "maximum drawbar-pull cut-off," either higher or lower, will develop a lesser drawbar-pull.

It becomes, therefore, apparent that some knowledge of the precise cut-offs or reverse lever positions, which at various speeds will result in the development of the desired maxi-

and information of engineers. This information is sufficient for them if they be careful, painstaking and understanding, but it must be freely admitted that the very neat selection of cut-offs from this card information cannot be expected or depended upon, because all attention possible may not be enough and engineers have other matters for their thought and time. It is suggested that the development of automatic means of taking care of this cut-off selection matter remains to be worked out, and there is reason for believing that several mechanical schemes for covering the matter will be developed into practical form, and that, in due course, engineers will be relieved entirely of attention to reverse levers and cut-off selection, except where less than maximum output is desired, under which conditions the engineer's mind will continue to be required, as at present,

for following instructions to "use full throttle until the shortest cut-off, meeting the speed and load requirements, or the least at which the engine will run smoothly has been reached and thereafter 'throttle' as necessary to meet speed

type of heater, effecting a saving of 15 per cent. He called attention to the incidental increase in boiler efficiency resulting from the lower rate of combustion and evaporation, which cause an additional gain of about four per cent. Mr. Basford expressed the opinion that the field for the trailer booster was not confined to freight locomotives, but on passenger power this device would prevent delays and improve operating conditions.

W. D. Wood (Fuller Engineering Company) submitted data to show the possibility of increasing efficiency by the use of pulverized coal. He stated that a mixture of bituminous coal with 38 per cent anthracite silt having a heating value of approximately 11,800 B.t.u. per pound, was developing an actual evaporation of 6.5 to 7 lb., or an equivalent evaporation of approximately 8 lb. per pound of fuel. The over-all efficiency of the boiler burning this pulverized coal ranged from 63 to 70 per cent.

requirements." Essentially these instructions are exhibited upon the back of the enginemen's card referred to, and shown herein as Fig. 5.

Discussion

W. E. Woodward (Lima Locomotive Corporation) referred to a recent comparison of electric and steam locomotives in which the average coal consumption per horsepower-hour for steam locomotives was given at 7.86 lb. The tests on which these data were based were conducted several years ago and the results of more recent road trials showed the comparable figure for modern locomotives to be between 3.4 and 4.0 lb., demonstrating that a considerable increase in efficiency had been effected in the last few years. Mr. Woodward pointed out that a reduction in the dynamic augment is a promising method of increasing the capacity and efficiency of locomotives. The limit of driving wheel loads has now been reached, but there is no reason why the static load cannot be increased if the pressure on the rail at the high speeds developed at present is not exceeded. By reducing the dynamic augment the weight on each pair of driving wheels could be increased 10,000 lb. and this increased weight could be utilized in capacity or efficiency increasing devices. The trailer booster gives a considerable increase in the drawbar pull, with a slight increase in weight and cost, and in Mr. Woodward's opinion represents the most practical method yet devised to utilize the potential boiler capacity of the locomotive at low speeds.

George M. Basford (Locomotive Feedwater Heater Company) referred to the fact that the stability of the railroads depends on whether railroad securities are attractive to the investor, and mentioned the appliances discussed in the paper as means by which the investment in locomotives could be made to bring a higher return. Describing the performance of feedwater heaters Mr. Basford stated that temperatures as high as 250 deg. F. had been obtained with the closed

RAILROAD LABOR BOARD APPOINTED

President Wilson on April 13 sent to the Senate the appointments of the nine members of the Railroad Labor Board, which is to have jurisdiction over disputes between railroads and their employees. After considerable discussion the appointments were confirmed on April 15 and the board was at once called together by the President.

The board is composed of three representatives of the public selected by the President, three representatives of the railroad companies selected by him from six names nominated by the Association of Railway Executives, and three representatives of labor selected by the President from 10 nominations by the principal railroad labor organizations. The board is to select its own chairman and secretary and is to have its headquarters at Chicago, although it is authorized to hold meetings elsewhere. The members appointed by the President are:

Public Group: G. W. W. Hanger, assistant commissioner of the United States Board of Mediation and Conciliation; Henry Hunt, former mayor of Cincinnati and a member of the board of trustees of the Cincinnati Southern; and R. M. Barton of Memphis, Tenn., a former member of the Tennessee court of appeals.

Management Group: Horace Baker, former general manager of the Cincinnati, New Orleans & Texas Pacific; J. H. Elliott, former general manager of the Texas & Pacific and later a colonel in the Transportation Corps, A. E. F.; W. L. Park, former vice-president of the Illinois Central and later vice-president and federal manager of the Chicago Great Western.

Labor Group: Albert Phillips, vice-president of the Brotherhood of Locomotive Firemen and Enginemen; A. O. Wharton, president of the Railroad Employees Department of the American Federation of Labor and formerly a member of the Board of Railroad Wages and Working Conditions of the Railroad Administration; and J. J. Forrester, president of the Brotherhood of Railway and Steamship Clerks, Freight Handlers and Express and Station employees.

Messrs. Barton, Phillips and Baker are appointed for a term of three years, Messrs. Hanger, Wharton and Elliott for two years, and Messrs. Hunt, Forrester and Park for a term of one year.

Mr. Hanger has had an unusually broad experience in dealing with labor and wage matters during his service with the United States Board of Mediation and Conciliation, to which he was appointed in 1913 by President Wilson. He was formerly chief statistician of the Bureau of Labor Statistics. During federal control of the railroads he was an assistant to the director of the Division of Labor of the Railroad Administration. The other two representatives of the public on the board have not been identified with railroad labor questions.

The three representatives of labor on the board are entirely familiar with the questions to be handled by the board, both through long experience as labor leaders and because of their connection with the wage propositions which were submitted to the Railroad Administration and are still in an unsettled state. Mr. Wharton has been a member of the Board of Railroad Wages and Working Conditions, which has investigated all wage questions for the Railroad Administration since the issuance of General Order No. 27 in May, 1918, and, under the practice of that board of alternating the chairmanship between the representatives of the management and of the labor organizations, he has twice been chosen as chairman.

Mr. Baker had been general manager of the Cincinnati, New Orleans & Texas Pacific, with office at Cincinnati, from 1906 to March 1, 1920. He entered railway service as a clerk in 1878 and had later been chief clerk, train-master, local freight agent, division superintendent, assistant general superintendent and general superintendent. Mr. Elliott began railway work as a messenger and was later an operator, despatcher, chief despatcher and transmitter. Subsequently he was employed on the Texas & Pacific, the St. Louis & San Francisco and other roads in various capacities in the construction and operating departments. In 1914 he was appointed inspector of transportation of the Texas & Pacific and later he was promoted to superintendent, general superintendent and general manager. Mr. Park has also come up through the ranks and has had a great deal of experience in labor matters on both the side of the employees and on the side of the management. He entered railway service in 1875 as brakeman on the Union Pacific and was later freight conductor and passenger conductor, serving as chairman of the grievance committee for the conductors for a time. In 1900 he was appointed division superintendent

and later general superintendent of the Union Pacific and in March, 1910, he was elected vice-president of the Illinois Central. In October, 1917, he was granted leave of absence by the Illinois Central for the duration of the war and was made first vice-president of the Chicago Great Western, later being appointed federal manager. He was a member of the board of arbitration that passed on the wage demands of the western enginemen and firemen in 1915.

Members of the board are to be paid \$10,000 a year.

The board is directed by the law to hear and decide any dispute involving grievances, rules or working conditions in respect to which any adjustment board fails to reach a decision within a reasonable time, or, if no adjustment board has been organized, upon the application of the chief executive of a carrier or of a labor organization or of 100 unorganized employees, or upon its own motion if it is of the opinion that the dispute is likely substantially to interrupt commerce. It is also directed to receive for hearing and to decide disputes with respect to the wages or salaries of em-

ployees or subordinate officials. Decisions by the board require the concurrence of at least five of the nine members and in cases involving wages or salaries at least one of the representatives of the public must concur.

JAMES H. MANNING

James H. Manning, for 16 years superintendent of motive power of the Delaware & Hudson, died at Albany, N. Y., on April 15, at the age of 58. Mr. Manning's personality as well as his ability may be said to have dominated to an unusual degree the motive power department of the road with which he was connected for so many years and his death is a severe loss to the road and to the employees who regarded him as much their friend as their superior.

Mr. Manning was identified with the motive power department throughout his entire career and was remarkably successful in the administration of the wide range of executive as well as mechanical problems with which he was confronted. His official position, however, did not prevent him from retaining a warm personal contact with a large number of his employees and more than one young man in his service has been surprised by a genuine expression of sympathy or offer of assistance from his chief when circumstances were against him.

Mr. Manning entered railroad service in 1876 as a machinist on the Union Pacific. He was appointed a gang foreman in 1883 and a general foreman in 1886. In 1890 he was made master mechanic at Omaha and in 1898 was transferred to Cheyenne, in the same capacity. In 1901 he engaged in the foundry business, but in 1903 returned to the railroads as assistant superintendent of rolling stock on the Canadian Pacific. In 1904 he was appointed superintendent motive power on the Delaware & Hudson.

In recent years Mr. Manning's position placed upon him the responsibility for applying the crucial test to some remarkable developments in locomotive design. The Mallet locomotive, pulverized fuel and the feedwater heater he tested with characteristic thoroughness and persistency. It may be recalled that when Mr. Manning first tested the Mallet locomotive that had supplanted two Consolidation engines on his road, he found that the Mallet burned considerably less coal than the two Consolidations, but rather than satisfy himself with this result, he attacked the situation one year later and succeeded in securing a fuel consumption on the Mallet that was less than the fuel consumption of either of the Consolidation engines that it had replaced.

Mr. Manning needed to be sure of his ground and when his course was clear he invariably pursued it with vigor and success. He was the type of man most needed by the railroads for the mechanical problems with which they have been confronted and his loss will be keenly felt.

J. H. Manning

A PRACTICAL FREIGHT TRAIN LOADING METHOD

A Simple Method for Finding the Car Factor and Equated Loading for Any Given Conditions

BY R. S. MOUNCE

Too strong emphasis cannot be placed on the importance of properly loading locomotives as a factor in increasing locomotive operating efficiency. It is almost obvious that a locomotive underloaded is wasting a portion of its hauling capacity and that one which is overloaded is retarding operation; in either case there is an economic loss.

Any train-loading method to be satisfactory must be easy to apply and should involve no loss of time in making up trains. For this reason no calculations should be left to the yard forces other than the necessary addition of gross car

both low grade and hilly railroads. The data have been reduced to graphic form where possible, and it is believed that the amount of calculation necessary to apply the method to specific conditions will be comparatively small.

Standard Loading Chart.—A standard loading chart showing the equated loading for an available drawbar pull of 10,000 lb. on grades from zero to two per cent, together with corresponding car factors, is taken as the basis for this train-loading method. A loading curve and its corresponding car factor are plotted for six different weather conditions in Fig.

Fig. 1—Standard Loading Chart for 10,000-Lb. Available Tractive Effort at Speeds Between 5 and 12 M.P.H. Under Various Weather Conditions

weights and the allowance for car friction. Allowance for car friction should be a constant quantity for a given weather condition on any division and of such a value that it will accurately equate any combination of car weights entering into the make-up of the train. It has been established that the friction allowance cannot be constant for all temperature conditions, because if it is correct for summer conditions it will be too small at low temperatures. This feature will be fully covered later.

The train-loading method given herewith has been thoroughly tested under a wide variation of weather conditions on

1. It is assumed that these loading curves are applicable to speeds of from five to twelve miles per hour over ruling grades.

Data for this chart are obtained in the following manner: Train resistances per ton for various car weights, as shown in the proceedings of the Master Mechanics' Association, for good average track conditions, were verified by further tests. These figures for 10 miles per hour were taken to be substantially correct for speeds between 5 and 12 miles per hour. The average increased train resistance per degree Fahrenheit drop in temperature has been shown by test to be .715 per cent.

The several temperature loadings are designated *A, B, C, D, E* and *F*, and the resistance per ton for cars of 70 and 20 tons gross weight as used in the chart are shown in the table below. The resistances for loadings *B* to *F*, respectively, are calculated, using the above data based on the figures 4.25 and 9.00 lb. per ton at loading *A*, for 70 and 20-ton cars, respectively.

Rating	Weather loadings		Resistance, lb. per ton, on level tangent track	
	Temperature range deg. F.	Average temp. deg. F.	70-ton cars	20-ton cars
A	50 and above	70	4.25	9.00
B	49 to 35	45	5.00	10.60
C	34 to 20	25	5.60	11.90
D	19 to 5	10	6.10	12.90
E	4 to -10	-5	6.50	13.80
F	-11 and below	-20	7.00	14.80

The formulæ used to derive the curves shown on the standard loading chart are:

70-ton cars—

$$\text{Train load (tons)} = \frac{P}{r}$$

$$\text{Number of cars in train} = \frac{P}{70 R}$$

20-ton cars—

$$\text{Train load (tons)} = \frac{P}{R}$$

$$\text{Number of cars in train} = \frac{P}{20 r}$$

$$\text{Car factor} = C = \frac{\frac{P}{R} - \frac{P}{r}}{\frac{P}{20r} - \frac{P}{70R}} = \frac{70(r - R)}{3.5R - r}$$

$$\text{Equated train loading} = \frac{P}{R} + \frac{PC}{70R} = \frac{P}{r} + \frac{PC}{20r}$$

Where *P* = Available tractive effort.

R = Total resistance, per ton for 70-ton cars.

r = Total resistance, per ton for 20-ton cars.

Applying these formulæ to one point on one of the curves, together with a check of the derived car factor to prove its accuracy in equating various car weights:

Assume:

Weather rating *A*

Equivalent grade, .5 per cent = *G*

P = 10,000 lb. (basic figure)

Then *R* = 4.25 + 20 *G* = 4.25 + 10 = 14.25 lb. per ton
and *r* = 9.00 + 20 *G* = 9.00 + 10 = 19.00 lb. per ton

$$\text{Car factor} = \frac{70(19.00 - 14.25)}{3.5 \times 14.25 - 19.00} = 10.7 \text{ tons}$$

$$\text{Equated train loading} = \frac{10,000}{14.25} + \frac{10,000 \times 10.7}{70 \times 14.25}$$

= 809 tons

$$\text{or} = \frac{10,000}{19.00} + \frac{10,000 \times 10.7}{20 \times 19.00} = 808 \text{ tons}$$

In this manner the series of equated train loading and car factor curves shown in Fig. 1 are derived.

Available Tractive Effort of Locomotives—Fig. 2 shows the per cent of the theoretical cylinder tractive effort at various piston speeds up to 600 ft. per minute for modern hand-fired locomotives, both with and without superheaters. These

curves are derived from reliable test data and represent good average locomotive conditions, and give a basis for calculating available tractive effort at various speeds for modern locomotives, by using the following data and formulæ.

$$\text{Piston speed (ft. per min.)} = 56 \times \text{m.p.h.} \times \frac{S}{D}$$

Where m.p.h. = Speed, miles per hour

S = Piston stroke, inches

D = Diameter of drivers, inches

Internal resistance of locomotive = sum of resistances of drivers, engine and tender trucks, and grade resistance.

$$1. \text{ Resistance of drivers, lb.} = W_D \times 22\frac{1}{2}$$

$$2. \text{ Resistance of engine and tender trucks, lb.} = (W_{ET} + W_{TT} + W_T) \left(3 + \frac{V}{6} \right)$$

$$3. \text{ Resistance due to grade, lb.} = W_{TOT} \times 20 \times G$$

Fig. 2—Percentage of Theoretical Tractive Effort Developed at Various Speeds

W_D = Weight on drivers, tons

W_{ET} = Weight on leading truck, tons

W_{TT} = Weight on trailing truck, tons

W_T = Weight on tender, tons

W_{TOT} = Total Weight, engine and tender, tons

V = Speed, miles per hour

G = Equivalent grade, per cent

Available tractive effort = cylinder tractive effort — internal resistance of locomotive.

For each class of locomotive for which train loading data are desired, a chart showing the available tractive effort at various speeds over the range of grades encountered, should be prepared. The following example shows how easily this can be done:

MIKADO TYPE LOCOMOTIVE WITH SUPERHEATER, CLASS S-4.

Cylinders	28 in. by 32 in.
Drivers	63 in.
Boiler pressure	180 lb.
Weight on drivers	240,000 lb.

Weight on leading truck.....	29,000 lb.
Weight on trailing truck.....	52,500 lb.
Weight on engine, loaded.....	321,500 lb.
Weight on tender, loaded.....	162,500 lb.
Weight on engine and tender, loaded.....	484,000 lb.
Theoretical tractive effort (at 85 per cent B. P.).....	60,900 lb.

Fig. 2 shows that the maximum tractive power is obtained from the starting speed up to a piston speed of 145 ft. per minute.

Substituting this value in the formula stated above:

$$145 = 56 \times \text{m.p.h.} \times \frac{32}{63}$$

m.p.h. = 5.1, speed below which locomotive will give maximum available tractive effort.

At this speed, 5.1 miles per hour, the available tractive effort on level tangent track will be:

$$60,900 \text{ minus resistances 1, 2 and 3.} \\ \frac{240,000}{2,000} \times 22\frac{1}{2} = 2,700 \text{ lb.}$$

$$\therefore \text{ Engine and tender trucks} = \frac{29,000 + 52,500 + 162,500}{2,000} \\ \times \left(3 + \frac{5.1}{6} \right) = 470 \text{ lb.}$$

3. Grade = 0

Sum of friction and grade resistances = 3,170 lb.

Available tractive effort = 60,900 - 3,170 = 57,730 lb.

For a three per cent equivalent grade at this speed, resistances 1 and 2 are the same as for level tangent track, but:

$$3. \text{ Grade} = \frac{484,000}{2,000} \times 20 \times 3 = 14,200 \text{ lb., and the} \\ \text{total friction and grade resistance} = 17,370 \text{ lb.}$$

Available tractive effort = 60,900 - 17,370 = 43,530 lb.

Plotting these two points on a chart, Fig. 3, and connecting them by a straight line, gives the available tractive effort over equivalent grades up to three per cent for locomotive Class S-4, at speeds below 5.1 miles per hour. Using the same formulae, available tractive effort curves for speeds of six, seven, eight, nine and ten miles an hour are plotted. These curves give complete available tractive effort data for Class S-4 locomotives. The same process is followed for the various classes of locomotives to be used, and these charts,

ing grade in one direction. Profile shown by Fig. 4, all grades compensated for curvature. The operating conditions on the AB division are assumed to be as follows:

Total time allowed for making a trip over the division in either direction, including terminal and road delays.... 8 hrs. 0 min.
Average terminal delays 1 hr. 0 min.

Fig. 3—Available Tractive Effort for Two Typical Locomotives Under Various Conditions of Speed and Grade

Taking water and other road delays 0 hr. 45 min.
Time left for making run within the eight hours 6 hrs. 15 min
Length of division 93 miles
Average speed over division 16½ m.p.h.

Northbound, the AB division has 46 miles of heavy ascending grade, 37 miles of low descending grade and 10 miles of level road. The descending grade and level portion can be covered in approximately one hour and 45 minutes, leaving four hours and 30 minutes to cover the 46 miles of ascending grade, over which the average speed will, accordingly, be slightly more than 10 miles per hour. This average speed

Fig. 4—Profile of the A-B Division

of the form shown in Fig. 3, together with the standard loading chart, Fig. 1, make further calculations unnecessary and the process of obtaining standard loading over any division a comparatively simple one.

Application of the Method to a Given Set of Operating Conditions—Case I.—Typical hilly division with heavy rul-

can probably be maintained if the train loading is based on a speed of nine miles per hour over the .76 per cent ruling grade.

Southbound this division has 37 miles of low ascending grade and 46 miles of heavy descending grade and 10 miles of level road. The run over the descending grade and level

stretches will not require over two hours, leaving four hours and 15 minutes in which to make the 37 miles of ascending grade, at an average speed of 8.8 miles per hour. At a speed of 8.5 miles per hour over the .2 per cent ruling grade, which is 13 miles in length, this average speed should be easily maintained.

Assuming that train loading is desired for Class S-4 locomotives over the AB division, the procedure is as follows:

Northbound.—From Fig. 3, for the Class S-4 locomotive, the available tractive effort at nine miles per hour on the ruling grade of .76 per cent is 42,250 lb. (4,225 x 10,000 lb.) The standard train loading chart, Fig. 1, gives the following data for 10,000 lb. available tractive power on a .76 per cent grade:

EQUATED LOADING FOR 10,000 LB. TRACTIVE EFFORT ON .76 PER CENT GRADE FOR VARIOUS WEATHER CONDITIONS						
Weather	A	B	C	D	E	F
Equated tons.....	565	550	540	534	530	525

Multiplying these figures by 4.225 gives the equated loading for the S-4 locomotive.

The car factor for a .76 per cent grade, taken to the nearest one-half ton is:

CAR FACTOR ON .76 PER CENT GRADE FOR VARIOUS WEATHER CONDITIONS						
Weather	A	B	C	D	E	F
Equated tons.....	7½	8½	9½	10	11	11½

Southbound.—In a similar manner, for a .2 per cent grade and a speed of 8.5 miles per hour, the available tractive effort = 46,100 lb. (4.61 x 10,000 lb.) The equated loading for 10,000 available tractive power on .2 per cent grade is as follows:

EQUATED LOADING FOR 10,000 LB. TRACTIVE EFFORT ON .2 PER CENT GRADE FOR VARIOUS WEATHER CONDITIONS						
Weather	A	B	C	D	E	F
Equated tons.....	1,570	1,480	1,405	1,345	1,305	1,265

CAR FACTOR ON .2 PER CENT GRADE FOR VARIOUS WEATHER CONDITIONS.						
Weather	A	B	C	D	E	F
Equated tons.....	21	23	25	26	27	27½

The final train loading, Class S-4 locomotive over the AB division would then be:

EQUATED TRAIN LOADING FOR CLASS S-4, TONS						
Northbound						
Weather	A	B	C	D	E	F
Car factor, tons.....	7½	8½	9½	10	11	11½
Equated tons, locomotive, Class S-4.....	2,387	2,324	2,282	2,256	2,239	2,218
Southbound						
Weather	A	B	C	D	E	F
Car factor, tons.....	21	23	25	26	27	27½
Equated tons, locomotive, Class S-4.....	7,235	6,825	6,475	6,200	6,015	5,830

Case II.—Typical low grade division. Profile shown by Fig. 5. All grades compensated for curvature.

The operating conditions on the CD division are assumed to be as follows:

- Total time allowed for one way trip over the division, including terminal and road delays 12 hrs. 0 min.
- Average terminal delays 1 hr. 0 min.
- Taking water and other road delays.... 2 hrs. 0 min.
- Time left for making run within the 12 hours 9 hrs. 0 min.

Length of division 138 miles
Average speed over division 15 ½ m.p.h.

Northbound the CD division has 68 miles of slightly ascending grade, 45 miles of slightly descending grade and 25 miles of level road. The run over the level and descending portions of the division can be made in about three hours, leaving six hours in which to cover the 68 miles of ascending grade, at an average speed of 11.3 miles an hour. On account of the general low grade nature of this division, the ruling portion of which is but .25 per cent northbound, this average speed can probably be maintained if the train passes over the two ruling portions, of six and three miles in length, respectively, at a speed of 10 miles an hour.

Southbound, this division has but 45 miles of slightly ascending grade, 68 miles of slightly descending grade and 25 miles of level road. The descending and level parts of the division can be covered in approximately four hours, leaving five hours in which to traverse the 45 miles of ascending grade, at an average speed of nine miles an hour. For the reason that practically all of this grade is about .2 per cent, the maximum southbound grade, nine miles per hour is taken as the speed over the ruling grade.

On account of the prevailing general low grade character of the CD division a smaller locomotive than the Class S-4 Mikado is to be used, the Class R-2 superheated Consolidation type locomotive having been selected. Data regarding

Fig. 5—Profile of the C-D Division

the available tractive effort for this class of locomotive are shown in Fig. 3.

Northbound.—The speed over the ruling grade is assumed to be 10 miles an hour. The available tractive effort at this speed over a .25 per cent grade is 29,000 lb., or 2.9 x 10,000 lb.

From the standard loading chart, Fig. 1, the loading data for 10,000 lb. available tractive effort on a .25 per cent ruling grade is found to be as follows:

EQUATED LOADING FOR 10,000 LB. TRACTIVE EFFORT ON .25 PER CENT GRADE						
Weather	A	B	C	D	E	F
Equated tons.....	1,195	1,140	1,095	1,060	1,037	1,012

The corresponding car factors are:

Weather	A	B	C	D	E	F
Car factor, tons.....	18	20	21½	22½	23½	24½

Southbound.—Similarly for a .2 per cent grade and a speed of nine miles per hour, the available tractive effort is 30,800 lb. or 3.08 x 10,000 lb. The equated loading for 10,000 lb. available tractive power on a .2 per cent grade and the car factors are:

Weather	A	B	C	D	E	F
Equated tons.....	1,570	1,480	1,405	1,345	1,305	1,265
Car factor, tons.....	21	23	25	26	27	27½

The final train loading for the Class R-2 locomotive over CD division would then be:

EQUATED TRAIN LOADING, TONS						
Northbound						
Weather	A	B	C	D	E	F
Car factor, tons.....	18	20	21½	22½	23½	24½
Equated tons, locomotive, Class R-2.....	3,465	3,305	3,175	3,075	3,005	2,935
Southbound						
Weather	A	B	C	D	E	F
Car factor, tons.....	21	23	25	26	27	27½
Equated tons, locomotive, Class R-2.....	4,835	4,560	4,330	4,125	4,020	3,895

The foregoing method of freight train loading is working out very well in practice. To apply it successfully, it is of course necessary to have an accurate knowledge of the operating conditions, and profile and topography of that portion of the railroad under consideration. It is to be expected that slight changes will, in some cases, be necessary in the loading figures assigned from the standard charts used, dictated, of course, by service trials of the predetermined loadings. The basic idea in presenting this method of train loading is to afford a reasonably accurate means of loading locomotives to their economic capacity, without necessitating extensive tests to determine equated loads and friction allowances.

LOCOMOTIVES FOR THE BELGIAN STATE RAILWAYS

On March 1 the American Locomotive Company at its Schenectady works completed the first engine of the order recently placed by the Belgian State Railways. The contract for this order, which calls for 150 locomotives, 75 to be built by the American Locomotive Company and 75 by the Baldwin Locomotive Works, was signed in Brussels on December 13. It was not until December 24 that the engineering department of the American Locomotive Company was furnished the information necessary to enable it to proceed with the design of the locomotive. The design was entirely new and the metric system was used throughout, yet in 52 working days the first locomotive was completed.

While the locomotives are of American design in all their

the front end. It carries 200 lb. steam pressure and has a copper fire box 96 in. by 60¼ in. All staybolts are of copper, with a tell-tale hole drilled in both ends. The firebox is supported at the front end by a sliding shoe, with a brass wearing plate and a large oil groove. The jacket is supported on a crinoline frame and is extended to the front end of the smokebox. A brick arch supported on tubes and a Locomotive Superheater Company's type A superheater are also included.

The counterbalance for the reciprocating parts was divided among the eight coupled wheels, and had to be such that the dynamic augment should not exceed 15 per cent of the static weight on the rail at 60 km. (37.3 mi.) per hour.

The last five of the locomotives to be built by the American Locomotive Company are to be equipped with Worthington feedwater heaters.

The tender frame is made of steel plate and is supported on three pairs of wheels held in rigid pedestals, the tender tank being arranged so as to drop down in between the frame.

<i>General Data</i>	
Gage	1.435 m. (4 ft. 8½ in.)
Service	Passenger and freight
Fuel	Bituminous coal
Tractive effort	15,800 kg. (34,800 lb.) at 65 per cent m. c. p.
Weight in working order	85,276 kg. (188,000 lb.)
Weight on drivers	75,750 kg. (167,000 lb.)
Weight on leading truck	9,526 kg. (21,000 lb.)
Weight of engine and tender in working order	138,619 kg. (306,000 lb.)
Wheel base, driving	5.941 m. (19 ft. 6 in.)
Wheel base, total	8.532 m. (28 ft.)
Wheel base, engine and tender	16.344 m. (53 ft. 8 in.)
Weight on drivers ÷ tractive effort	4.79
<i>Cylinders</i>	
Kind	Simple
Diameter and stroke610 m. by .711 m. (24 in. by 28 in.)

Consolidation Type Locomotive for Belgium Built in Record Time

details, as will be noted from the photograph, the Belgian type of cab and tender were used. This was done in order to permit the American locomotives to couple with the existing Belgian tenders and vice versa. The Belgian State Railway's standard train connection of the screw link type with two spring buffers, the international system of threads, and French-Westinghouse brake equipment with French-Westinghouse pipe threads were also included.

These engines are to be used in both freight and passenger service and are designed for 16-deg. curves and a maximum grade of 3.3 per cent. Following European practice, all the engines are built for left-hand drive. All gages are graduated in kilograms per square centimeter.

The specifications called for a weight on drivers of 164,000 lb., weight on truck of 22,000 lb., total weight of engine 186,000 lb., and a weight limit per axle of 42,900 lb. The official scale weights are as follows:

First driver	41,600 lb.
Second driver	41,600 lb.
Third driver	41,900 lb.
Fourth driver	41,900 lb.
Total drivers	167,000 lb.
Truck	21,000 lb.
Total engine	188,000 lb.

The boiler is of the straight top type, 68 in. in diameter at

Water capacity	24,000 litres (6,350 gal.)
Coal capacity	7,000 kg. (7.72 tons)

*Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.

CAR DEPARTMENT

PNEUMATIC FREIGHT CAR PAINTING MACHINE

BY NORMAN McCLEOD

Considerable objection has arisen against a number of paint spraying machines used in painting freight cars, the workmen complaining of inhaling the spray when operating these appliances due to the operator having to stand too close to the outlet of the sprayer. In order to eliminate this seri-

ous feature, which imperils the health of the men, a machine has been so designed that the operator stands a considerable distance from the object being painted. This device also has the advantage of allowing the painter to have quite a lengthy pipe in his hand, the nozzle or sprayer being on the farther

end and a considerable distance from his face, while with the ordinary spraying machine the spraying pipe or nozzle is practically no farther removed than the length of the operator's arm. The machine consists of a cylindrical $\frac{3}{16}$ in. steel tank $11\frac{1}{2}$ in. by $26\frac{1}{2}$ in. inside dimensions, mounted on a wheelbarrow framework which facilitates handling. The filling of the tank with paint is done with a funnel through

General Arrangement of the Paint Sprayer and Details of the Atomizer

ous feature, which imperils the health of the men, a machine has been so designed that the operator stands a considerable distance from the object being painted. This device also has the advantage of allowing the painter to have quite a lengthy pipe in his hand, the nozzle or sprayer being on the farther

a large filling hole located on top of the head. Cleaning, inspection or repairing is facilitated by the removable top head held in place by four hook bolts and made air tight with a leather gasket.

After filling the tank with the required amount of paint

air pressure (80 to 90 lb. per sq. in.) is introduced in two places, first through a 1 in. check valve and a perforated 1 in. pipe at the bottom of the tank and an auxiliary $\frac{3}{4}$ in. connection leading off from the 1 in. by 1 in. by $\frac{3}{4}$ in. tee between the main supply globe and check valves to a tee on

a $\frac{1}{2}$ in. vertical pipe in the top head. At this tee the air is diverted allowing pressure to go in the top of the tank and to the atomizer, where it is joined by the paint, brought to the atomizer through a $\frac{3}{8}$ in. pipe the end of which reaches within $\frac{1}{2}$ in. of the bottom of the tank.

CHARACTERISTICS OF SOFT METAL BEARINGS*

Discussion of the Properties Resulting from Different Compositions and Pouring Temperatures

BY W. K. FRANK

A BEARING may be defined as that member of a mechanical device which constrains a moving part in its travel. The most common type is the axle or journal bearing used in all machines having rotating journals. It may completely surround the journal or may cover only a portion of it. The journal may rotate continuously, may rotate intermittently, or may have reversing rotation. The bearing may be subjected to pressure from one direction only, as in electric motors; alternating pressure, as in engine

dirt or at an intense heat; often improperly aligned and momentarily required to reseat the shaft. Roller bearings are admirably fitted for certain classes of service, but the necessity of the balls or rollers being made and maintained in a condition of extreme accuracy, measured in ten-thousandths of an inch, makes them impractical under the heat at which a rolling-mill bearing or wrist-pin bearing operates. The inherent limitations of design of the rolling type prevent any considerable adjustment to compensate for the wear, which

Tilting Furnace in a Bronze Foundry

crank-pin bearings; or alternating pressure, combined with reversed rotation of the shaft, as in engine wrist-pin bearings.

It may be well to show, in passing, the position covered by plain bearings—that is, those of sliding contact—as opposed to ball- or roller-bearings, called bearings of rolling contact. Plain bearings furnish a rugged construction which is subjected to every kind of mistreatment to which a mechanical part is heir, and in the great majority of cases they do their work satisfactorily. They operate under heavy impact, continuing perhaps a thousand times a minute and 24 hours a day; in acid fumes; sometimes with scanty lubrication; under

does occur, and the replacement of this product of the highest mechanical skill requires an expenditure which is not inconsiderable.

The reduction in friction, and consequent saving in power, effected by rolling bearings is a potent argument in their favor, and were it not for the limitations of application for the reasons given, this type would have found much more general application. It will, therefore, be seen that plain bearings serve a particular field and that they are called upon to render service under trying conditions.

Properties of Bronze and Babbitt Bearings

The material from which a bearing is made plays a large part in design. While bronzes and babbitts are the principal

* From a paper presented before the Engineer's Society of Western Pennsylvania. The author is vice-president of the Damascus Bronze Co., Pittsburgh, Pa.

materials used, cast-iron, wood, fiber, etc., answer for some conditions. Very little wear has been observed from some cast-iron bearings, but it should be noted that good lubrication was provided and the pressures and rubbing speeds were low. The choice between babbitt and bronze will be made from considerations of speed, pressure and temperature of operation, as will be shown later. Babbitts are softer and have lower melting points than bronzes, and are therefore adapted to conditions of lower pressure and temperature. Bearings subjected to impact should not be made from babbitts, because of the malleability of these alloys. The lower melting points and malleability of babbitts are, however, the properties that make them easy to handle and they are for

Pit Furnaces Operated with Oil and Gas.

this reason widely used. Accurate bearings may be secured without expensive machining, or they may be die cast and made into intricate shapes without any machining whatsoever. Their plastic character allows them to conform to the load and prevents localized pressures. Bronzes, on the other hand, have comparatively high melting points and are, therefore, not so easily handled. They are generally furnished by a bronze foundry in the form of castings, whereas babbitts are supplied in ingot form for application directly by the equipment builder and user.

Bearing metals are essentially a mixture, the components of which are distinctly different in hardness. In these metals the softer crystals are abraded faster and develop into depressions, allowing the harder ones to stand above them and support the load. These softer crystals perform another function also. A bearing should be plastic to a limited degree, since fitting is more or less of a rough approximation. Furthermore, a change in alinement of the shaft will produce points of concentrated pressure and the bearing must be capable of reseating itself to distribute its load properly.

Another bearing requirement is that it shall protect the shaft against injury. Unfortunately, wear is always an attendant evil of motion, and it is preferable that the bearing wear rather than the shaft. In most designs the bearing is the less costly part and is the more easily replaced, hence its harder element should be softer than the shaft. The bearing should also be of such a nature that it will not grip or be capable of welding itself to the shaft in case it becomes heated, as serious damage will be done should this occur.

It will, therefore, be seen that the range of selection for bearing metals has been greatly limited by these considerations. The use of pure metals has been excluded because of the necessity for components with greatly dissimilar wearing

properties. We are, therefore, dependent on alloys, and on those alloys of which the harder crystals are softer than the shaft; which are capable of conforming to the load and yet able to carry it without rupture or undue distortion; and which do not tend to weld on heating. Other considerations require that these alloys conduct and radiate the heat of friction readily, that they wear slowly and show small friction and that they be capable of uniform production.

The only alloys we know of which combine the desired properties are the bronzes and babbitts. Babbitts fall into two general classes—namely, the tin-base metals and the lead-base metals. Antimony, copper and zinc are the principal ingredients with the tin and lead, but sodium, cadmium, calcium, barium, bismuth, nickel or aluminum are added in some cases.

The tin-base, or so-called "genuine babbitts," are variations of Isaac Babbitt's original formula of 89.3 per cent tin, 3.6 per cent copper, 7.1 per cent antimony, and they vary in the percentages of all of these elements and sometimes contain lead or other metals. In these alloys the tin furnishes a plastic matrix, in which are embedded the harder crystals of the tin-antimony, copper-tin or copper-antimony compounds.

A microphotograph of a tin-base metal is shown in Fig. 1. The dark background is the plastic tin matrix, the cubical crystals the tin-antimony compound and the six pointed "snow crystals" the copper-tin compound. In the lead-base alloys the hard crystal forming elements are principally antimony

Fig. 1. Tin-Base Babbitt, Magnified 75 Diameters, Etched with Five per cent HNO_3 .

and tin. The matrix is lead, an alloy of lead and tin, or the lead-antimony tin eutectic, and the hard crystals are usually the antimony-tin compound.

In Fig. 2 is shown a typical lead-base structure, with the soft eutectic forming the supporting medium for the hard, cubical, tin-antimony crystals. In the case of lead hardened with sodium, cadmium, etc., these elements probably form compounds with the lead, the compounds constituting the hard crystals embedded in the lead matrix. Lead-base babbitts present a wide range of compositions and are commonly composed of lead, tin and antimony. With a variation possible in each of these elements, it may easily be seen that almost an infinite number of combinations may be made. The lead is varied between 65 and 90 per cent, the tin between 0 and 40 per cent and the antimony between 5 and 20 per cent. Varying physical properties are obtained by different formulas, and selection of the proper one is determined by the character of the load, hardness of the journal, lubrication, pressure and speed.

Babbitts are covered by tentative specification B 23-18 T of the American Society for Testing Materials (Table 1). The physical properties appended to the specification (Table 2) do not form part of it, but are merely to be taken as infor-

mation regarding the properties that might be expected from carefully manufactured alloys. It will be seen that the Brinell hardness (all Brinell figures in this paper refer to a 300-kilogram load on a 10-millimeter ball, applied for 30 seconds) varies from 14.3 in the lead-base to 34.4 in the tin-base, and that the deformation with a load of 10,000 lb. varies from 0.007 in the tin-base alloys to 0.285 in the lead-base alloys. These properties indicate why tin-base alloys are preferred for some services, in spite of their higher cost.

It has been pointed out that pouring temperatures of bab-

bitts largely influence their resistance to continued impact. The properly prepared tin-base alloys showed little difference in this particular from the properly prepared lead-base alloys, but it was stated that the allowable pouring temperatures of the tin-base babbitts showed a greater range than the temperatures for lead-base babbitts. The former are, therefore, more often properly poured and show better properties.

Babbitts as a class show high plasticity combined with low Brinell hardness and compression strength, and these properties limit their application. Bronzes are, therefore, used where higher physical properties are desired to resist pressure or impact, or to provide longer service. Whereas, in the case of the babbitts the softer element is the major constituent, so in the bronzes it is the minor constituent. Bearing bronzes are, in general, copper-tin matrices filled with lead. The term bronze applies strictly to a copper-tin mixture as differentiated from brass—a copper-zinc mixture. These terms are frequently loosely used, and it is quite common to speak of bearings as "brasses." On the other hand, manganese bronze,

and the explanation given is undoubtedly the proper one. In the case of a bronze bearing metal of 90 copper, 10 tin, we secure a mixture of at least two dissimilar crystals and possibly three. In the case of copper and zinc, only one set of crystals is formed, up to a high zinc content. A homogeneous mass is formed as contrasted with the non-homogeneous mass of hard and soft elements in the copper-tin alloy, and the latter mixture is desirable because of the formation of the minute oil reservoirs. The shop man will tell you that, in a bearing, brass is dry and harsh as compared with bronze, and it is undoubtedly the property of providing oil cells that gives bronze its value as a bearing metal.

Copper-tin mixtures have good hardness and compression strength. An increase is noted with additions of tin up

Fig. 2. Lead-Base Babbitt, Magnified 75 Diameters. Unetched

to about 30 per cent, although at about 12 per cent brittleness begins, owing to the increase in the eutectoid or "bronzite" constituent. Some bearings which require high compressive strength contain more than 12 per cent tin, but they should be used with caution. The 90 copper, 10 tin alloy shows Brinell hardness of about 70 and compression of 0.20 on a one-inch cube under 100,000 lb. per sq. in.

The majority of copper-tin bearings contain less than 12 per cent tin and combine hardness with ductility. They are limited to service where alinement is good, as they do not possess sufficient plasticity to conform readily to a shifting load. They find use in some machine tools and similar equip-

"Tobin" bronze and a multitude of other so-called bronzes are in reality brasses, to which possibly one or two per cent tin has been added; and aluminum bronze is usually a mixture of copper and aluminum, sometimes with a small quantity of iron.

The American Society of Mechanical Engineers Committee on Bearing Metals recently pointed out why bronze is preferred to brass in bearings. This has long been understood,

ment, where good alinement may be maintained, and are used abroad on some railroad equipment where speeds and pressures are not excessive and where fitting is carefully performed. With ideal service conditions, a copper-tin bearing will probably outwear bearings containing added metals, but in most classes of service localized pressures caused by changing alinement will produce rapid wear and heating in this composition. Zinc is sometimes added to copper-tin mixtures,

and the familiar gun-metal is composed of 88 copper, 10 tin, 2 zinc, but the most widely used bearing mixture is the copper-tin-lead bronze.

In bronzes containing lead, the reservoir-forming property is further enhanced. The lead does not combine with the copper-tin structure, but is only mechanically held by it in the form of globules. It imparts plasticity to what would otherwise be a more or less rigid structure, in addition to furnishing it with additional oil reservoirs.

A typical copper-tin-lead bronze is shown in Fig. 3. The light colored matrix is the harder copper-tin structure, while the light globules surrounded by dark margins are of similar composition, but richer in copper and softer than the matrix. The black globules are the lead and are still softer. It will,

Fig. 3. Copper-Tin-Lead Bronze, Magnified 100 Diameters. Etched with $H_2O_2 + NH_4OH$

therefore, be seen that three distinct hardnesses are present. In this mixture we maintain the hard, wear-resisting points of the copper-tin alloy and can vary plasticity by varying the lead content. The lead can be added up to 50 per cent, and this variation gives the different properties required by varying classes of service. In some cases a very small quantity of lead is added. It produces hot shortness and is therefore not desirable in hot-mill bearings. These may run at very high temperatures, and bearings containing much lead will break under the pressures encountered. A typical low-lead formula of this type would be 91 copper, 8 tin, 1 lead.

At the other end of the scale are found the high-lead mixtures containing up to 30 per cent lead. They find limited application because of their high plasticity and consequent distortion. They answer well the requirement of protecting the shaft, but do not, on the other hand, transmit heat readily. They show rapid wear, as is evident to anyone who has examined a pile of scrapped railroad car bearings. The high-lead bearings can be readily distinguished from the moderately leaded ones by the extent to which the axle collar has worn into the ends of bearings of the two classes. High-lead mixtures were originally designed to replace the babbitt-lined railroad car bearings, but do not possess sufficient plasticity to accomplish this and are used with babbitt linings. Because of this lining they seldom come in contact with any part of the journal, excepting the collar, and their length of service is determined by the life of the lining, distortion of the back and collar wear.

It is, moreover, true that high-lead mixtures are difficult of uniform production. Since the lead is but mechanically mixed with the copper-tin alloy, and as lead has a much higher specific gravity, segregation to a greater or less degree is liable to occur in the crucible and mold. Lighter castings which cool quickly can be made with some degree of success,

but lead segregation of heavy castings is an accepted evil. Auxiliary agents, including nickel, ferro-manganese and sulphur, are used as preventatives of segregation, but these are not reliable expedients. Referring again to the scrap pile—the testing laboratory of experience—bad segregations in fractures of a large number of high-lead bearings are revealed. While it is not stated that castings cannot be produced without segregation, it is true that this mixture is easily mishandled and bad bearings result. Unfortunately, low initial cost has recommended it to some users. Conservation of tin during the war led the United States Railroad Administration to specify high-lead bearings for the new cars purchased. The bearing manufacturers will benefit by the replacement that will inevitably be required. A typical mixture consists of 65 copper, 5 tin, 30 lead.

As in many matters, the best lies between the extremes, and in this case the moderately leaded bronzes best answer most bearing requirements. They can be produced uniformly and well, as no great difficulty is experienced from segregation of the lead. Alloys of this class range from 5 to 15 per cent lead, and 12 to 7 per cent tin, with the remainder copper. Copper, tin and lead all tend to form oxides readily, and deoxidizers are often added. Phosphorus is the most effective of these, and is usually added in quantities in excess of that required for deoxidization and produces an additional hard constituent in the bronze. Phosphor-bronze, as the resulting alloy is called, is one of the most valuable of alloys in present-day use, for a great variety of requirements. It presents a comparatively hard surface, and yet is sufficiently plastic to conform to moderate changes in alinement. It answers all the essentials of a good bearing, for moderately good conditions of service. The standard formula calls for 79.7 copper, 9.5 lead, 10 tin, 0.8 phosphorus, and should specify less than $\frac{1}{2}$ per cent impurities, as too often scrap metals are compounded to produce this alloy and the resulting trouble is charged to the formula, rather than to the impurities contained. For varying degrees of hardness the lead and tin may be varied between certain well-defined limits. The standard formula shows Brinell hardness 60, and compression of 0.25 on a one-inch cube under 100,000 lb. per sq. in.

As far back as 1892 Dr. Dudley of the Pennsylvania Railroad determined the practical limitation of lead content for car bearings to be in the neighborhood of 15 per cent. Later work on this subject has not altered the conclusions he reached in this respect, and it may be of interest to note that 27 years later a table of railroad specifications shows the net average content of 15 per cent lead and 8 per cent tin. Dr. Dudley's experiments were real service tests. It should be remembered, however, that while the $12\frac{1}{2}$ per cent lead and 15 per cent lead alloys wore more slowly than phosphor-bronze in railroad car bearings, this is not conclusive proof that the lead is in itself a wear-retarding element. Lead furnishes the means of allowing the bronze to conform more readily to varying alinement and, by preventing localized pressures, reduces wear. Under the comparatively low pressures and absence of impact, but with the changing alinement of car axles, the 15 per cent lead alloy shows superiority; whereas, under high pressures and impact the phosphor-bronze shows slower wear. It is necessary only to compare the pressures of car axles of 325 lb. per sq. in. of projected area with pressures of 3,500 lb. per sq. in. of projected area, encountered in rolling-mill practice, to demonstrate why 15 per cent lead alloys are not suitable for the latter condition.

Heavy cuts in machining may seriously injure a bearing bronze. Some years ago trouble was experienced by heating in the driving-wheel bearings in new locomotives of one of the railroads. Our company had furnished the bearings and we were called upon to explain the trouble. Chemical analysis of the bronze was made and found satisfactory. The fracture revealed nothing to the naked eye, but when a section was

polished and placed under the microscope the condition shown in Fig. 4 was noted at the machined edges; whereas, normal structure, as in Fig. 5, was found in the interior points. It was then apparent that heavy cuts in machining had actually forced a large part of the lead from the copper-tin-sponge, and a rigid structure was the result. It was suggested that $\frac{1}{8}$ in. be machined from the bearing journal surface to eliminate this distorted metal, and after this was done no further heating was experienced.

Some explanation should be made of the lack of suitable bearing testing machines. It is true that some machines have

Fig. 4. Distorted Bearing Bronze, Magnified 100 Diameters. Un-etched

been designed, but their value lies mainly in the testing of the lubricant. It is practically impossible to duplicate service conditions on the present types of apparatus and, from the foregoing discussion of variations in lubrication and of shifting pressures, this may be understood. With imperfect lubrication, large differences on the same identical test bearing will be noted on different days, and the explanation probably lies in the varying approaches to perfect lubrication obtained.

Tensile and compression tests are sometimes employed to check the uniformity of a given formula, but their extended use is more or less limited by considerations of the expense

Fig. 5. Normal Bearing Bronze, Magnified 100 Diameters, Unetched

involved. Analysis is commonly used to check the desired formula, but even this is faulty. The same formula may show large variations in structure caused by different pouring temperatures, or rates of cooling. Structure is obviously the factor which determines the bearing value and, while a microscope may show the arrangement of the elements, it does not measure hardness or plasticity. The Brinell or other hardness value does not give much information. Little can be expected at present from inspection tests.

As in many other fields, a reliable manufacturer should be consulted for his experience with similar conditions. When suitable alloys are obtained he should be required to maintain uniformity of properties in the alloys subsequently delivered. It should be pointed out that the use of scrap mixtures is a common source of the varying service obtained in bearings and that uniform results can be obtained only from alloys composed of new metals, produced with standardized melting and molding practice. Unfortunately, initial price considerations sometimes rule in the purchase of bearing alloys, and the final cost per unit of service is much higher than would be the case with a slightly higher initial outlay.

Discussion

In the discussion following the presentation of this paper, John S. Unger, manager of the Central Research Bureau of the Carnegie Steel Company, stated that he believed the common practice of purchasing bearing metal of either bronze or white metal by analysis was wrong. He expressed the opinion that all bearing metals should be purchased on their mechanical and physical properties, for the reason that these properties in the same metal may be decidedly influenced by the number of times the metal has been remelted, by the pouring temperature and the size and volume of the bearing. His opinion was based on the fact that the temperature at which a soft metal bearing is poured exercises a pronounced influence on the ductility of the metal, as is readily shown by the tensile strength, compression, hardness and wearing properties.

T. B. Lynch stated that his experience had been that if soft metal was poured at too low a temperature it crumbled under the compression test; when poured at 450 deg. C it showed good ductility, and when poured at a dull red the test would shear off with an angular break or crack and burst. He stated that his observations did not agree with the temperatures recommended by others, who advised pouring some six lead-base metals at 330 deg. C, and suggested that further investigation be made to determine the best pouring temperatures for the several classes of soft metals.

(The second section of this article, dealing with lubrication, will appear in the June issue.)

KILN DRYING OF GREEN HARDWOODS

Technical note No. 90, issued by the Forest Products Laboratory, United States Forest Service, points out the need for a mechanically perfect heating system in kiln-drying hardwood lumber green from the saw. The successful kiln-drying of such lumber requires a very even control throughout the kiln at all times, variations in temperature of even a few degrees or variations in relative humidity of 0.5 per cent seldom being permissible. Such uniformity is possible only when the heating coil is properly drained, is relieved of air, and is distributing heat uniformly along its length.

It is the contention of the Forest Products Laboratory that the return-bend heating coil system, by bringing about more uniform distribution of heat in the kiln, enables the operator to obtain quicker and better drying than is possible with the header-coil system as it is generally installed.

The return-bend heating coil gives practically an even heat distribution under any steam pressure. The header-coil produces different temperatures at either end of the kiln, the extent of variation depending on the steam pressure, length of coils, drainage, traps, etc.

Refractory hardwoods require low temperatures, and the lower the temperatures used, the more evident will be the difference in the results obtained with these two types of heating equipment. Under the same careful operation, green hardwood lumber may be turned out from kilns using the one type satisfactorily dried, and from kilns using the other type, over-dried at one end and under-dried at the other.

FREIGHT CAR REPAIRS ON THE E. P. & S. W.

An Outline of General Policies that Have Brought Results With Details of Some of the Work Done

BY A. M. DOW

General Foreman, Freight Car Repairs, El Paso & Southwestern

A PRACTICAL REVIEW of the methods of carrying on the work in general on the El Paso & Southwestern as well as some of the detail parts of the work, may be of practical use to those in charge of the car departments of the railroads. Let us consider first the work of the light or running repair forces, who are working directly under one of the assistant general foremen of freight car repairs. The repair track inspector begins work 20 min. before the men every morning and carefully checks the bad order cards,

Fig. 1—Wooden Cars Completely Rebuilt On a Seven Hour Schedule

and inspects the cars to see that all defects are marked up on the cards as a guide to the men in working the car. One track is worked out completely, then the force works back on another track, and so on over the five different tracks during the eight hour period. A switch engine pulls off all cars that are finished at the noon hour, and at such other times as needed. So far as the light or running repairs are concerned, the methods in use are not very different from any other repair points, except that not more than two men are allowed to work on one job at a time. There is no necessity of more than two men for any light repair work, and, if more than two men are on a job, we find they are in one another's way to such an extent as to be a detriment rather than a help.

While this regular day's program is being carried out by one of the assistant general foremen and his force, the other assistant general foreman and his force are engaged in repairing the wrecked cars, heavy steel repairs, rebuilding and reinforcing old wooden equipment, etc. The two assistant general foremen change places every 30 days in order that each may keep in full touch with the entire force and all the different classes of the work. It is also found that the men remain at a higher point of efficiency through the change of supervisors.

Systematizing Heavy Repairs

To illustrate the method used in handling our heavy work it may be interesting to describe in detail the rebuilding of a series of 250 steel underframe wooden superstructure stock cars, which was undertaken and carried through at what we consider a very rapid rate, and at a very economical labor

cost per car. The work was systematized in the following manner: A schedule was figured out composed of a series of individual operations. On each one of these operations were placed just enough men to perform that operation in a period of time which was previously determined upon as the unit of the schedule. In the case of this series of cars it was desired that one of these cars be turned out of the shop complete in every respect every four and one-half hours, which was done, at an average labor cost of \$15.07 per car. The schedule was arranged as follows:

Gang No. 1. Four men stripped the superstructure of the car, removing all decking, all broken, decayed, or crooked posts, and side and end plates, in fact stripping the car completely.

Gang No. 2. Three men erected the framing complete, and applied all tie rods.

Gang No. 3. Three men applied the outside slats and roofs.

Gang No. 4. Two men applied the inside slats, running boards, doors, and safety appliances.

Gang No. 5. Two men did all truck and steel work.

Gang No. 6. Two men made side doors and did air brake work.

Gang No. 7. One man painted the car.

In all seven gangs with a total of 17 men turned out a complete car every four and one-half hours, at a labor cost of \$15.07 per car. This is a record of which we were proud. It is true this work was done in 1915, and that the average wage paid per hour was 19.7 cents. The majority of the men could not speak our language, and, with the exception of three or four men, up to the time we hired them and placed them on this work, had never done car work of any kind.

After completing this series of stock cars the task of applying steel center sills and rebuilding a series of 82 all

Fig. 2—A String of Steel Underframe Cars After Rebuilding

wood box cars was taken up. These cars required new side sills, plates, posts, decking, all siding, etc. In fact, they were built entirely new from the sills up, with an inside metal roof. (See Fig. 1.) Seven hours was set as a schedule, with eight operations and a total of twenty-seven men, and this work was done at an average labor cost of \$45.36 per car. Then followed the rebuilding of a series of 100 steel underframe box cars, shown in Fig. 2, which were put through on a six hour schedule. These schedules were

rigidly maintained, and a number of workmen were weeded out as the work progressed on account of not keeping up with the procession.

Routing Cars and Material

A word as to how the work was kept moving. All heavy work of this kind on which a schedule can be successfully

Fig. 3—A Badly Bent Sheet In the Flanging Clamp

used is laid out on repair tracks which open on a transfer table on one end and to the repair track lead on the other. The cars are brought in over the transfer table and started

Fig. 4—The Sheet Shown Above Fifteen Minutes Later

down the track. When the first operation is completed, the men move the car ahead one car length, and so on down the

used in each operation is conveniently placed for the gang on that operation to reach.

The secret of the success of the schedule plan lies in the fact that each man performs only one operation, and that one over and over again. As he gains experience and practice in performing that operation he begins to try to make it easier to perform, knowing that as he succeeds in doing so he also makes the work easier for himself, thus, unconsciously, speeding up the machine as a whole. The necessity of teaching a workman one operation only makes possible the use of inexperienced men on practically the entire job. Another gain made is that the different gangs will unconsciously promote rivalry by the exercise of that pride that exists in almost every man of not letting the other fellow beat him, thus each gang striving not to be last really keeps the whole moving smartly and rapidly. The schedule plan also helps out the labor situation in this day of shortage of mechanics, as it is our practice to use the experienced men

Fig. 5—Flanging a Floor Sheet In the Power Brake

on light or running repairs, and the less capable men on the work which can be placed on a schedule as just outlined.

Steel Car Repairs

The subject of heavy steel car repairs seems to be side-stepped by most of the car men who write for technical magazines, not because of its lack of importance for this is the most important work of the car department. Perhaps the subject can best be handled by giving a general description of some of the most important points. For instance, a side sheet of a gondola car is often badly bent and possibly rolled up by being cornered or wrecked. Experience has shown that the only way to handle a case of this kind is either to take out the entire sheet and straighten it cold on a face plate with clamps, or else cut out the damaged

Fig. 6—Application of Tandem Spring Draft Gear on Center Sills with Wide Spacing

track until all operations are finished, when the switch engine removes the cars from the track and takes them to the paint track where painting and stenciling is done. The material

portion and put in a new piece by making a butt splice.

In any case when attempting to straighten plate steel such as is used in the floors, sides, and ends of a gondola car, do

not attempt to use heating appliances such as oil burners and torches, as the trouble will only be aggravated. These plates must be straightened cold on face plates, and by the use of powerful clamps, aided by a liberal use of hand power in the shape of heavy sledges. In Fig. 3 is shown

in operation forming a floor sheet for a 40 ton steel gondola car, which is being put through the shop for new floors, the old floors being corroded and rusted through. In connection with renewing the floors in these cars it was found that the side sheets were also rusted through at a point just above side sill. In order to avoid applying new side sheets we used plate steel wide enough to flange upward on the side sheet

Fig. 7—Jacking Stall for Straightening Steel Cars

Fig. 9—Defective Bolsters Prepared for Welding

a clamp in use to straighten all parts of steel cars. This is in reality nothing but a boiler shop flanging clamp.

The photograph shows a badly bent side sheet of a gondola car in position in the clamp for straightening cold. Fig. 4 shows the same plate 15 min. later, having been straight-

16 in. from the top of the side sill and riveted to the side sheet by a row of 1/2 in. rivets spaced 6 in. apart. This makes a very neat job, and also makes the side sheets just as good as new ones, as corrosion of the side sheets does not extend more than 6 in. above the side sill.

These cars were built in 1903 and the center sills were

Fig. 8—Construction of the Jacking Frame

ened by the clamp, and three men with sledges, in that period of time.

In Fig. 5 is shown a bending brake on which it is possible to bend cold, to any desired shape, plate steel up to 1/4 in. in thickness by 10 ft. long. In the foreground may be seen various shapes which have been formed cold on this machine. It has been found to be of great benefit in our steel car work. In the illustration the machine is shown

spaced 24 in. apart, and equipped with a twin spring draft attachment which was continually failing. To overcome this trouble it was decided to change the draft gear to the tandem spring type using the heavy type G spring. This was accomplished by applying a cheek plate made from 3/8 in. steel, as shown by Fig. 6. This has proved very satisfactory, and stopped draft gear trouble with this series of cars.

Frequently steel, or steel underframe, cars are found with

the center construction badly out of line, or the sides badly buckled. These cars are taken to the jacking frame, Figs. 7 and 8, where they are readily straightened without stripping. This frame can be constructed at a nominal cost, and will soon pay for itself in the economies effected. Jacks may be used at any angle desired, and from as many different angles, simultaneously, as one may see fit.

Some of the work done with the oxy-acetylene welding plant is shown in Fig. 9. Built up truck bolsters on which the ends have been worn through, are shown in the foreground. Enough of the bolster is cut out to remove all the worn parts, then new metal cut to fit the original contour

Fig. 10—Part of the Equipment for Handling Steel Car Work

is welded in. Cracked cast steel bolsters are welded and then patched over the weld.

A part of our steel car fabricating machinery, forges, and face plates used in repairing steel car detail parts are shown in Fig. 10. Fig. 11 shows the nature of some of our steel car repairs.

Keeping the Output Up

The car plant, as reviewed in this article, and shown in the cuts, is capable of handling all repairs and rebuilding, as well as building new any equipment that might be needed on a road of the size of the E. P. & S. W., if efficiently handled, and efficiency is a matter that our supervisory forces must become more proficient in than ever in these days when mechanics are made by an order and perpetuated by an agreement. We must use every endeavor to get every return

Fig. 11—Steel Cars Dismantled for Repairing

possible for the money spent for labor, ever remembering that any force of men will give results in direct proportion to the desires of their supervisors, and that, if any of our shop forces are not up to the standard output, or unit cost, the trouble is in their supervision, or something that the supervisor can correct. Do not put up that excuse which of late has become so popular, "The men will not do a day's work any more," but instead ask yourselves the question *why* they will not, and then proceed with the remedy. If the remedy is bitter, take it in small doses until you have effected a permanent cure, or else acknowledge to yourself that you are out of place as a supervisor and retire to a

sphere where you are on common ground with your surroundings.

If above the need of a remedy, or having taken it, and are yourselves above reproach along these lines, then unite in condemning to your superiors the past practice of car construction to the end that future equipment may be constructed strongly and correctly, then protected from shocks by some improved shock absorbing device, instead of as in the past when the theory of constructing the different parts stronger each time new cars were built was followed so far that as a result at the beginning of government control we were constructing cars on the theory of a battering ram wherein the stronger destroys the weaker, and the poor car man was blamed for not keeping his equipment in service instead of requiring those responsible for design to properly design and *provide protection* from the shocks and rough handling they, as well as all of us, knew the car would receive when placed in service.

The thousands of cars built prior to about 1912 and put in service without any means being taken to protect them from the shocks it was known they would receive stand as a monument to prove that our practice has been wrong in the past, and our ways should be mended at once. We should take some of the remedy called "self analysis," and may possibly derive some benefit from a consistent course of this treatment.

PERIODICAL REPACKING OF JOURNAL BOXES A.R.A. RULE 66

BY CAR INSPECTOR

Numerous papers have been written on the subject of hot boxes, the causes and remedies therefor, and various methods of packing journal boxes have been introduced, but nothing has been offered which will eliminate the trouble entirely. Just as soon as an epidemic of hot boxes appears and trains are seriously delayed everyone on the railroad, from the president down, gets busy and the trouble is temporarily relieved. This would indicate that careful attention as to repacking and lubricating is necessary at all times. It has been clearly demonstrated that unless journal boxes are properly packed journals will not lubricate, resulting in heating of the brass. If not detected in the early stages of heating, the journal as well as the brass, wedge and in many cases the journal box also will be damaged to such an extent as to require renewal. An important duty rests upon the shoulders of the car oiler and just how well he performs his work can be very readily judged by glancing over the hot box reports.

Too much of the work of administering care to journal boxes has been left to the car oiler in the train yards and not enough attention given this class of work on repair tracks and in shops. M. C. B. Rule 1 requiring that the same attention be given foreign cars as the owner's cars has not been fully carried out in this respect and the fact that cars are away from home oftentimes two and even three years, renders necessary some action which will assure better attention for the foreign car. A. R. A. Rule 66 which makes the car owner responsible for periodical repacking of the journal boxes should be an inducement to care for the foreign car and if the work is properly performed in accordance with the provisions of this rule there is no question but what a remarkable improvement in the condition of journal box packing will be noted. It should be borne in mind, however, that the results which will be obtained, depend entirely upon the manner in which the work is done and the supervising force in the car department has an important duty to perform in carrying out the provisions of this rule. The practical value of all A. R. A. rules can be greatly enhanced by more care in living up to them.

THE INSPECTION OF FREIGHT EQUIPMENT*

Air Brakes and Foundation Brake Rigging; Estimated Braking Power; Defects of Arch Bars and Trucks

By L. K. SILLCOX

Master Car Builder, Chicago, Milwaukee & St. Paul

TO PIPE cars properly is of vital importance to the desired action of the air brake. This, however, is a portion of the air brake make up which is occasionally neglected. Under no condition should the pipe be used without first being thoroughly cleaned. To do this the pipe should be lightly tapped to loosen the scale and dirt and then be blown out with steam or air. The sizes of pipe given in the air brake catalogues should in all cases be strictly adhered to. It will be noted that sizes of pipe given for freight cars are generally larger than those to be used on passenger coaches, as shown below. This is for several reasons.

(1) It will cause a more rapid reduction or increase of pressure at the rear portion of the train on account of air traveling through the large pipe more quickly; the larger the pipe the less friction the air will encounter in its passage through it.

(2) A freight car is considerably shorter than a passenger car, thus the large pipe makes the volume of air in the train more nearly equal to that in the smaller pipe used on the passenger coaches, which are longer.

When pipes are cut a flare or fin will be created in the inside of the pipe, considerably reducing its size; this in all cases should be carefully removed with a reamer. When too many of these are allowed to remain through the pipe system it will prevent the emergency action of the brakes. When using red lead or any other substance to make a joint, it should always be put on the outside thread or the thread to be screwed in, as this will prevent it from being forced into the pipe and causing defects in the brake system.

Whenever practicable, when necessary to change the direction of the pipe, it should be done by long, easy bends, instead of elbows or short bends, as the frictional resistance caused by these fittings retards the flow of air through the pipes. Care should be taken to have all the pipes rigidly clamped, so as to prevent vibration or moving, which causes the joints to leak or holes to become chafed in the pipes. After the pipe work is applied and completed it should be thoroughly tested under full pressure for leaks by use of soap suds applied to the joints, and later painted with rust-proof paint.

Cars will not be accepted in interchange unless equipped with air brakes having 1¼-in. air brake pipe and angle cocks, also quick action triple valve, pressure-retaining valve and an efficient hand brake.

Pipe Clamps

Pipe clamps should be checked at every opportunity both on repair tracks and in yards, to see that they are so placed and in the necessary condition to perform the work for which they were intended. They should be securely fastened to a rigid part of the car and should hold the piping firmly, prevent vibration and not allow the brake pipe to shift lengthwise if air hose are pulled apart, as happens in a break in two or when switching in the yards. Any missing jam or lock nuts must be replaced.

Air Hose

It is required that all air hose must be tested under air pressure with soap suds at every available opportunity whenever air pressure is to be had. This practically only applies

to repair tracks, but much difficulty is experienced in the outside yards where a soap suds test is not practical, and therefore defective hose is hard to locate. Inspectors should be very careful in their inspection of hose on cars in the yards and should remove every one that shows an older date than 27 mo. if they do not consider it safe to proceed, and of course this only applies to hose which otherwise appear to be in good condition. Any of these hose that are removed on account of being old date should be forwarded to the main shop in the district so that they may be properly tested.

It should also be the duty of all inspectors to pick up all defective hose, regardless of the nature of the defect, and forward them to the general storekeeper. A great many of these defective hose, especially burst hose, will be found in cars and cabooses, and inspectors should make a periodical inspection of this equipment, so that they may know positively that there is no defective hose lying loose in their district.

At No. 1 and No. 2 inspection stations air hose must be tested with soap suds, and if found in a porous condition is to be replaced. Air hose gaskets must be kept in good condition, and when new ones are inserted the retaining groove must be cleaned out with the tool provided for that purpose. The opposite end of this tool, which is formed in a loop, is to be employed in seating the gasket in place. Air hose in service more than 27 mo. are generally in need of replacement.

Brake Cylinders and Reservoirs Loose on Their Supports

Whenever indications point to a cylinder and reservoir being loose on their supports, or if any of the cylinder or reservoir bolts are loose or gone or lock nuts needed, repairs must be made at once, as movement of these parts causes brake pipe leakage and breakage. When brake cylinders and reservoirs are to be tightened on their supports, run up two or three of the nuts only far enough to bring the bolting flange into light contact with the supports. Then, with the bolting flange in contact with the supporting brackets at each hole, line up with cut washers where required. A failure to do this will result in springing and cracking the auxiliary reservoir and springing brake cylinders out of round.

A great deal of difficulty is experienced on account of reservoirs breaking away from cylinders and holding brackets on cylinders and reservoirs breaking off. While the class of supports used on many cars in service is at fault, the majority of the difficulty which is being experienced could be overcome if a little more care were taken in drawing up the nuts of the supporting bolts. It is common to see the men draw the nuts up until the cylinder and reservoir are in full contact with the support, thereby bringing an undue strain on the equipment. If where the supports are out of alignment the carmen were instructed, before tightening the nuts, to merely draw the reservoir up until the bolting flange was in light contact with the support and then line up with cut washers whenever necessary, the danger of breakage would be lessened considerably.

Triple Valves

There are six types of triple valves in general service, namely the Westinghouse, H-1, H-2, K-1 and K-2 and the New York F-1 and H-2. All of these valves work in con-

* Fifth of a series of articles on this subject by Mr. Sillcox. Copyright 1920 by the Simmons-Boardman Publishing Co.

junction with one another and are interchangeable to the extent that the H-2 Westinghouse and New York can be applied to a car that formerly had the K-2, but the H-1 Westinghouse and F-1 New York could not be used in this instance as one is a ten-inch valve and the other is an eight-inch valve. Otherwise there is no difference in the working of the valve.

Brake Rigging

Brake heads and brake shoes should be carefully inspected to see that they are in good condition and keys properly in place. Should brake shoes be worn out at either end permitting the head to wear against the wheels, the brake shoes should be renewed. When brake shoes are worn irregularly they should be reversed to obtain the maximum service from the metal in the shoe.

Brake hangers should be inspected at the brake head to see that they are not worn, making them unsafe; this should also apply to the hanger at the truck connection, to see that the hook or eye are not worn to the unsafe limit. Brake wheels, brake ratchet wheels and brake ratchet pawls should be inspected to see that they are properly retained in place when repairs are being made and careful inspection is to be made to see that they are properly maintained. Bolts and pins used in connection with hand brakes should be in place and properly secured.

Adjusting Brakes

After checking up piston travel if it is found necessary to re-adjust the brakes, the first thing to be done is to close the cut-out cock in the crossover pipe and bleed the auxiliary reservoir, this to prevent injury. The adjustments must be made so that the live truck levers on both sides of the car travel the same distance, to insure an equal distribution of braking power. With the brake applied, the foundation brake rigging should be inspected to see that all levers have ample clearance in their guides and elsewhere to prevent striking or binding with 12 in. piston travel, that all cotter keys are in place and points well spread, that hangers and dead letter fulcrums are secure, that the brake levers are standard, that rods are not being cut by axles, and that the rigging in general is in good order.

Before making any changes to provide lever clearance, insure that the length of rods and guides and the location of the latter are standard for the car. Whenever inspecting cars, inspectors must make sure that the brake rods are not riding on the axles thereby making them liable to break on application of the brakes.

Piston Travel

By piston travel is meant the distance the brake cylinder piston moves out when the brake is fully applied. To measure piston travel first be sure that the head is bottomed in the cylinder, making a mark on the piston rod at the edge of the cylinder head and then note the distance the piston travels out when the brakes are applied. Standing travel is the distance the piston is forced out in an application of the brake upon a car when not in motion. Running travel is the distance the piston is forced out in applying the brake upon a car when in motion. The running travel is always greater than the standing travel, the increase due to slack in loose fitting brasses, to the shoes pulling down on the wheels, to play between boxes and pedestals and to everything of a similar nature that increases lost motion in the brake rigging under the influence of the motion of the car. False travel is an excessive travel momentarily occurring while the car is in motion. It is due to unevenness of the track or to some unusual temporary strain.

The brake cylinder pressure resulting from a common train pipe reduction is greater with a short than with a long piston travel. A piston travel of eight inches results in a brake cylinder pressure of about 50 lb. in a full service ap-

plication. Inasmuch as running travel is generally about 1½ in. greater than standing travel, the standing travel should be 6½ in. to secure this result while running. If the piston travel is shorter than eight inches, the auxiliary and brake cylinder air will equalize at a higher pressure and the brakes will be applied much harder. If the travel is more than eight inches, the auxiliary and brake cylinder air will equalize at a lower pressure and the brakes cannot be applied nearly as hard.

Brake Leverage

Ability to figure brake leverage is an accomplishment for an air brake man, not always a necessity, but it is well to know something about it. The different kinds of levers and the manner in which they operate should be learned first. A lever of the first kind has the power applied at one end, the weight to be moved at the other end and the fulcrum in the center. The cylinder lever connected to the push rod and top rod is a lever of the first kind.

A lever of the second kind has the power applied at one end, the fulcrum at the other end and the weight to be moved is between them. The live truck lever of an outside hung brake is usually a lever of this kind.

A lever of the third kind has the power applied between the ends. A lever of this kind takes more power in proportion to the weight to be moved than either of the other kinds. This lever is very rarely met with in the present construction of freight cars.

When measurements and calculations of brake power are made, the greatest care must be exercised in measuring, as a mistake of a very short distance on the short end of a live lever will alter the power considerably.

Beginning at the brake cylinder where the power is first exerted, the power must be ascertained, which is done by multiplying the area of the cylinder piston by the pressure per square inch. The result of an eighth-inch cylinder is 2,500 lb. and a ten-inch cylinder, 3,900 lb. This value is then multiplied by the distance from the push-rod connection to the fulcrum, which is in the center, this lever being of the first kind, and this product is divided by the distance from the fulcrum to the top-rod connection. This will give the pull on the top rod, which is transmitted to the top of the live truck lever, usually a lever of the second kind. This pull is next multiplied by the total length of the live truck lever and the product is divided by the length of the short end, which will give the strain on the brake beam. This multiplied by the number of beams will give the total braking power. To determine what per cent the car is braking the total braking power is divided by the light weight of the car. Caboose should brake approximately 45 per cent of their light weight, other freight cars 60 per cent.

Both cylinder levers, or cylinder and floating lever, need not be of the same length, but they must be of the same proportion to insure getting the same braking power on both ends of the car.

Brake Levers

When necessary to apply a new lever to a system freight car the proper dimensions of the lever wanted must be ascertained positively in order to provide the proper braking force to the wheels. The dimensions of the various levers for the several types of cars are clearly shown on blueprints and must be closely followed.

Lever Pins and Cotter Keys

The greatest care should be exercised at all times to know that lever pins are properly in place and cotter keys applied and properly opened to prevent the pin being jarred out, which would cause a brake rigging failure and probably a derailment, especially if it occurs in the bottom rods. Lever

pins should be placed in from the top whenever possible, as this will provide a certain amount of protection in case the cotter key works out. Brake beam hanger pins also should be checked over closely to ascertain whether the pin by continual friction is worn through and liable to break at any time. It would be good policy, whenever possible, to have brake hanger pins removed for inspection, as investigations disclose the fact that a great majority are about half worn through. At any rate, inspectors and repair men should check them very closely, as there is nothing that tends more to cause derailments than brake beams coming down.

Cotter Pins, Split Keys and Nuts of Brake Hanger and Connection Bins

It should be remembered that these parts must be placed with the heads inside or under, so as to make the retaining cotter pin, split key or nut visible from a passing inspection, and not make it necessary for inspectors to climb under the car to note their condition.

Brake Beams

The dimensions and proportions governing the hanging of brake beams are as follows: The height when measured from the top of the rail to the center of the face of new shoes is: For inside hung brake beams, 13 in.; for outside hung brake beams, 14½ in.

The spacing from center to center of brake heads is 60 in., with an allowable variation of ⅛ in. in either direction. Attachments for safety hangers shall be 51 in. from center to center.

The angle of the lever fulcrum shall be 40 degrees from the vertical.

The lever pin hole shall be either two or three inches in front of the top of the brake head lugs. The variation in either direction from straight and true shall be not less than 1-3/32 in., nor more than 1½ in. in diameter.

Safety Hangers

It is required that all brake beam safety straps on car trucks shall be of such depth as to allow but ¾ in. between the straps and the bottom of the brake beam when the brake shoe is ¾ in. from the wheel, and of such length that no part of the brake beam will strike the strap when the brake is applied with all shoes worn to a minimum thickness. It is also required where angle iron brake beam safety supports are employed that not to exceed ¾ in. clearance is to prevail between the bottom of the brake beam and the top side of the safety angle.

The capacity and strength of the number one beam is suitable for cars weighing less than 35,000 lb. The number two beam to be used on cars weighing over 35,000 lb., although it is permissible to use the number two beam on cars weighing less than 35,000 lb. Right and left-hand brake beams are designated as follows: When facing the back of the brake beam with the center strut pointing away from the observer, if the top of the lever slot inclines toward the right it is known as a right-hand beam, and if the top of the lever slot inclines toward the left it is known as a left-hand beam.

Brake Shoes

It should be borne in mind that at each application of new brake shoes the piston travel changes. Therefore, whenever new shoes are applied to cars the piston travel should be checked up accordingly.

Hand Brakes

In checking up cars before leaving repair tracks and yards, it should be known that all hand brakes are released, for if cars are allowed to leave with the hand brake set there is a liability of slid flat wheels, or at any rate overheated wheels, and the eventual possibility of bursting. Also, it should be noted that the hand brake rod and chain are not too long.

They should be of such dimensions as to insure a full application of the brakes with the use of the hand wheel. The chain must not catch on the staff support and rods, levers, etc., and must be free from any interference that would prevent the delivery of full hand brake force to the brake shoes. Brake chains or rods must not bear against any part of the axle, causing chafing and wear.

Hand Brake Staffs

Hand brake staffs must be made of one piece; welding of two or more parts together is not permitted. The standard maximum height of the brake staff for standard box cars, from the top of the rail to the top of the brake staff, is 14 ft. The portion of the brake staff on which the brake chain winds must be of such length and so located as to permit winding the amount of chain resulting from 12-in. piston travel without "piling up" or overlapping.

The dimensions of the brake chains should be, for the first link that fastens on brake staff, ½ in. diameter, 2 in. long, and 13/16 in. wide inside. For the succeeding links, 7/16 in. diameter, 1¼ in. long and 5/8 in. wide inside measurements. This chain is attached to the brake staff with a ½-in. bolt, which is riveted over after the nut is applied.

Hand brakes must be known at all times to be operative and effective; a failure of this appliance constitutes a violation of the federal laws, therefore proper inspection and maintenance are absolutely necessary.

Running Repairs to Trucks

It seems to be the general experience that there is a great deal of trouble, due to failures of truck frames on account of nuts missing from box pedestal jaw and column bolts, and in many cases it is necessary to apply new bolts on account of the worn or otherwise damaged condition of the threads. It is also found that on practically all types of trucks a great many brake hanger bolts and pins are found that have no spring cotters, split keys or nuts to hold the bolts or pins in place, the result being that the bolts or pins fall out of the hangers and allow the brakebeams to drop; also, the hangers and pins are allowed to become worn to such an extent that in their weakened condition they fail. Care must be exercised in examining brake hangers to see that flaws in forgings do not exist, also that the brake heads are not worn beyond the required limits.

Another point is that a large percentage of the brakebeams in service have no safety device for holding them in case the hanger or pin should break, with the result that it is found necessary to employ extra men in the yards to watch these important features of truck inspection and maintenance. On account of the great amount of this work in large terminals, it appears that generally some stations are not giving all the attention that they can to maintaining these essential parts of trucks while passing through their hands, the result being that extra work is placed upon their neighbors.

The matter of truck maintenance should be taken up vigorously by all supervisors and the attention of inspectors and repairmen called to seeing to it that the nuts on oil box, pedestal jaw and column bolts are all applied and kept tight and also that the brake hanger bolts or pins are equipped with a suitable lock nut, spring cotter or split key. The failure of these parts is causing much trouble, and no reasonable expense should be spared in properly maintaining them.

Investigations carried on from time to time have developed that after the removal of brake hangers and pins from a number of cars they were found to be about half worn through. It is apparent that these parts have been in service for a long time and that they are very rarely, if ever, inspected except when brakebeams or hangers fail. It is a paying practice, whenever cars reach repair tracks, to have all the brake hanger pins and bolts removed for inspection and renewed when found necessary.

With this end in view, therefore, a system should be in-

augurated at all stations whereby all cars reaching repair tracks will have the trucks carefully locked over and the renewal made of any parts showing undue wear. Particular attention should be given to the column and oil box bolts and nuts—in fact, it should be our purpose not to allow any car to leave a repair track without the trucks receiving a thorough going-over and being put in good repair.

For system cars the standard brakebeams furnished are equipped with three openings, namely, for the pot hook hanger, for the intermediate stirrup type hanger and for the center supervision hanger, with the thought that the brake hanger can be changed in case the pot hook eye is worn, thus avoiding the necessity of having to change the entire brakebeam. It is further desirable to see that nuts on tension rods of brakebeams are kept properly locked in place and tightened.

Defective Arch Bars and Truck Frames.—Permissible Methods of Welding and Repairing.—Arch bars should be inspected for cracks, especially in bends. This may be more effective after first giving the edge of the arch bar several taps with the inspector's hammer to loosen up rust at cracks and flaws, which can then be more readily detected. Seams and flaws are usually found at the bends and at column bolt holes, especially at the bottom of the column post on the edge of the arch bar. Arch bars should not be welded in the bend or at bolt holes or between the journal box or column and box bolt holes. Trucks with cast steel side frames, such as Bettendorf, Andrews, Vulcan, Scullan, Ajax and others, should be gone over carefully to discover flaws or cracks that might exist which would endanger their safety. The same tapping with the hammer as on arch bars should be required on cast steel side frames. These frames are not considered safe for service when found cracked or with flaws more than *one inch back from the edge of the frame*. Such frames should be repaired by welding with oxy-acetylene or with electric welding apparatus, or they should be replaced with a new casting.

The fact that so many cast steel side frames and cast steel bolsters are failing in the tension (lower length of the truss) members is conclusive evidence of weakness in design, and the welding of the fractures will not add to the strength but is likely to introduce a condition of further weakness by improper workmanship and change in the structure of the metal. It is, therefore, necessary to confine acetylene or electric welding within specified limits on structures, subject to alternating stresses, as experienced in truck side frames and bolsters. The parts which are to be repaired must not be welded unless removed from the car or truck. Truck bolsters, however, may be welded in place by removing the truck from under the car body. The entire crack should be burned or chipped out far enough back so that there will be no portion of the crack in the metal. Failure to do this permits the check or crack to work its way across the metal to the farther side, due to the constant vibration, even after the weld has been made. A hole may be drilled at the end of the crack or check and chipped or burned towards the hole. The surfaces where new material is to be deposited must be clean and bright and reasonably smooth, and therefore if surfaces are prepared by the burning process the surfaces must be finished by chipping or welding. The portion of the part adjacent to the fracture should be heated before the welding is begun. In welding, the operator should begin to weld at the point farthest away from the outside edge and work the weld towards the edge. When truck sides and bolsters are welded, the weld must be made smooth and the following record legibly stamped on the weld with at least $\frac{3}{8}$ -in. steel stencils in the following form:

No. Day Year Road
Shop Symbol Welders No.

Truck bolsters and spring beams should be carefully inspected to see that they are secured to place properly and are not cracked or broken, making them unsafe for service.

Arch Bars and Truck Frames Bent

Derailments and other classes of road failures often cause trucks to be allowed to go into service temporarily with arch bars and frames bent laterally in the center; this is not only dangerous but a regrettable practice.

Side Bearing Clearance

Side bearing clearance should be carefully observed on cars with metal body and truck bolsters. When balanced on center plates it is considered good practice to have clearance of $\frac{1}{16}$ in. to $\frac{1}{8}$ in. between all four side bearings. If they are bearing hard on one side the total clearance should not be more than $\frac{1}{4}$ in. on the opposite side. On cars with wood body and truck bolsters, or composite wood and metal bolsters, it is considered good practice to have $\frac{1}{8}$ in. to $\frac{1}{4}$ in. clearance between all four side bearings.

Care of Journal Box Lids

Lids on journal boxes should be lifted to make inspection of the sponging, journal bearings and journal bearing wedges to see that they are in proper condition, and journals not cut. Journal bearings and wedges should be in proper position in the box and sponging in place well to the back of the box and up under the journal. Box lids should fit well in place and be properly secured to exclude dirt and dust.

Truck Brake Rigging

Brakebeams, brakebeam connections and brake hangers should be carefully inspected to see that they are in good condition, with brake connection pins in place and cotter or split keys properly applied and opened. Brake levers and lower brake connecting rods are to be inspected to see that they are in good condition and the brake pin cotters split.

Brake heads and brake shoes should be carefully inspected to see that they are in good condition and the keys properly in place. Should brake shoes be worn out at either end permitting the head to wear against the wheels, the brake shoes should be renewed. When brake shoes are worn irregularly they should be reversed to obtain the maximum service of metal in the shoe.

Brake hangers should be inspected at the brake head to see that they are not worn, making them unsafe; this should also apply to the hanger at the truck connection, to see that the hook or eye are not worn to the unsafe limit. Brake shoes which are broken away or not safe must be replaced, and shoes unevenly worn must be turned. Brake shoes must be properly located and in place and not allowed to ride on the flange of the wheel. Brake shoes showing signs of being burnt red must have the brakes on such cars tested for proper operation and wheels examined for heating cracks.

Hand brakes should be tested to see that they are in operative condition and the brake chains not too long to prevent fouling when brakes are applied. Brake chain links should not be less than $\frac{3}{8}$ in. in diameter at any point.

The brake wheel, brake ratchet wheel and brake ratchet pawl should be inspected to see that they are properly retained in place when repairs are being made, and careful inspection is to be made to see that they are properly maintained.

Cars built after October 1, 1914, and prior to January 1, 1917, will not be accepted in interchange unless equipped with either the No. 1 or the No. 2 M. C. B. brakebeam, as indicated by the light weight of the car; the No. 1 beam must not be used on cars having a light weight in excess of 35,000 lb. Cars built after January 1, 1917, or cars receiving general repairs after October 1, 1918, must be equipped with metal brakebeams of not less than the capacity of the No. 2 M. C. B., or stronger, as the conditions may require.

All of the M. C. B. brakebeams referred to shall have the letters "M. C. B." and proper number plainly stamped or cast on the strut, as required by the specification.

After October 1, 1920, cars will not be accepted in interchange unless equipped with all metal brakebeams.

SHOP SCHEDULING VS. OLD-FASHIONED METHODS

BY SUPERVISOR

The question is often asked, "What is the difference between running a locomotive repair shop with a schedule system or in the regular way as usually done?" It may be answered as follows:

The old-fashioned method of getting output from a railroad shop was to bring in engines until the shop was as full as possible. In a transverse shop with 25 stalls, two small engines were placed on some stalls, blocking or cramping the passage ways at the front and rear of other engines, crowding in, say 35 engines. In a longitudinal shop with accommodations for 25 engines on two outside tracks, five or six engines would be put on the central or wheeling and transfer track, blocking the passage of wheels and engines going out. Also engines are crowded in so closely together on all three tracks that spaces between them are narrowed or closed entirely. Probably there would be 35 engines in this shop also.

The next step was to date the completed engines out and begin repairing those shown to go out first. Soon a cylinder is wanted, or a steel deck casting, or some unusual part, and these are not found in stock. This engine is then abandoned for the time being and the men are told that another more promising engine will come ahead and all hands go to that engine, transferring tools, material, etc., and they all take plenty of time to make notes and begin over again, studying the needs of this new engine. Material must be hunted up, and in some cases material from the first engine which is bolted to the lathe or planer is taken off and other material for the second engine substituted. Perhaps another switch is made from this second engine on account of delayed material, a welded frame tongue in the smith shop, a new link in the machine shop or heavy boiler work develops. In like manner possibly every other engine in the 35 undergoes a similar process of being worked on for a while and later deserted.

To sum up the situation, the unsystematic, inefficient shop superintendent gets what he can out of his shop, full to overflowing with engines and material. The men and supervision are demoralized. There is no penalty except tempestuous talk and driving for not getting an engine out on the date set; simply pick another good one and get that. The higher officers are continually disappointed; they expect a certain engine out on a stated date and don't get it. This

old-fashioned organization with 35 engines on 25 pits in the shop finally succeeds in delivering 25 engines with classified repairs by the end of the month. This means an output of one engine per pit per month, or, based on 35 crowded pits, 7-10 of an engine per pit per month.

Now a railroad repair shop is, or should be, as carefully designed as a Mallet engine. A Mallet will give its maximum drawbar pull with minimum steam consumption, at a working speed of about 15 miles per hour. Likewise a modern railroad shop will, at the present time, deliver its maximum output at the rate of about two engines per pit per month, with minimum cost and minimum labor and machine effort. But how about the shop delivering 7-10 of an engine per

stall per month? It is not possible, unfortunately, to figure accurately the cost and lost time and labor resulting from an output ratio of this low figure.

Let us now consider the modern shop operated with the assistance of a complete scheduling system. Engines are

thoroughly inspected before being brought into the shop, and all material needed is on the ground, not simply on requisition. The policy of the management for this shop is to allow the shop superintendent to bring in engines at his discretion, and the line-up is not dictated by some higher officer. Twenty-five engines, inspected and chosen for properly balancing the work of the shop organization, are then brought in on the 25 pits available and exactly in accordance with the space designed for placing engines when the shop was built. Dates are then set for these engines to go out completely repaired and every operation and all important material is scheduled to be finished at certain proper times in order to erect the engine in the most orderly and systematic manner. The output is figured at the low estimate of 50 classified repairs for the month, or two engines per stall or pit.

Now comes the most important feature of this properly operated shop. When an engine drags for some reason, the cause is sought out and immediately remedied and those responsible for the condition are penalized with red delay marks on the schedule office boards and the daily delay sheets advertise to all superiors and supervision the department which is delinquent and the cause. What is the result? Foremen are not pleased with this situation, and take steps at once to line up their material and forces to rectify it. No man with any ambition at all wants to be known as a slacker or as having "fallen down" on his job and caused others to be late and censured. Men are **not** shifted from this late engine as was done in the old-fashioned shop. This

Shop men frequently complain that locomotive output is limited because of a lack of pits. The author of this article thinks the fault lies elsewhere.

would be the easiest way out and following the line of least resistance, but the most costly way in the end, as is always the case through life. Everyone is stimulated by the supervision, including the shop schedule supervisor, to appreciate their responsibility for meeting the promises made to superiors for the delivery of the engine on time. Consequently they all "go to it" with energy and a quiet determination to overcome the obstacles speedily. Responsibility is the greatest sobering influence, and a proper sense of responsibility is what we need in our shops today.

The primary beneficial result from these up-to-date methods is character development. The shop superintendent and foremen and all the way through the ranks, begin to realize and understand that when an engine is scheduled out, that settles it, and the engine must be worked on continuously and faithfully until it goes out, barring the most unforeseen reverses, even if a week late. Gradually the general status of the whole shop is raised, the morale of the supervision and men improved and a desire to win stamped on every mind. This spirit and desire for honest orderliness and conscientious work is the only known condition through which a shop may be developed to produce the output for which it was designed. It is admitted, of course, that adequate machines and organization are first installed. Shorter hours, abolition of piece work and social unrest have their influences, but fundamentally the above discussion is logical and conclusive.

SALVAGING HIGH SPEED STEEL SCRAP

BY SAMUEL S. BUCKLEY

The process used by the Onondaga Steel Company for reclaiming high speed steel scrap is based on a careful selection and grading of the material to be reclaimed. To be successful, the converter of high speed steel scrap must return to the customer a steel that is as good if not better than the original high speed steel, and it is not wise to endeavor to produce any other than the required standard. The converter must be guided in his action to a great extent by the type of steel submitted, the larger proportion of which will contain 18 per cent tungsten, about 4 per cent chromium, approximately 1.20 per cent vanadium and carbon between .60 and .70 per cent. Being held to the standard type, he has no opportunity of improving this steel by a change in composition.

The converter of high speed steel scrap has had to overcome the notion that because scrap is used as a base the steel produced must be of inferior quality. Satisfactory results have been attained, however, only by the use of extraordinary methods in the selection and proportioning of new material, and extreme care in handling it through all the steps of the process. The idea that only scrap is used in melting is erroneous. No matter how carefully tested and selected the scrap may be, new additions of muck bar, tungsten, chromium, vanadium, etc., must be made to "sweeten up" the melt, as a steel maker would say. If high speed steel scrap were melted without this sweetening, the resulting material would have lost some of its elements, particularly vanadium which is quite volatile, and it would be apt to show shortness or brittleness, possibly from the same reason that cast iron becomes more brittle each time it is melted over. The scrap received is separated into either first, second and third class, or is rejected.

The first class comprises high speed steel scrap containing 15 per cent tungsten or over. The second class consists of scrap with between 15 per cent and 12 per cent tungsten. The third class, which has some value, though hardly worth converting, consists largely of the old-fashioned self-hardening or mushet steel.

Rejected material consists principally of the straight car-

bon tool steel and odds and ends of ordinary soft steel and discard that would ordinarily be classed as junk. In these rejections are included drills, reamers and other tools with soft steel shanks, oil tube drills having copper or brass oil tubes, tools that have shanks or parts brazed or soldered upon them. Tools with soft steel shanks can be partially reclaimed by breaking off these soft steel parts well into the high speed steel. The reason for the rejection of the above mentioned soft steel parts is due, of course, to the fact that they are usually made of nickel steel, and nickel as well as copper or any other non-ferrous metals are absolutely tabooed in high speed steel, therefore the maker dare not chance the addition of even a small percentage of any of them.

The Spark Test

In order to develop an absolutely uniform material from the miscellaneous scrap sent in, it is necessary for every piece to be tested by some quick, economical and reliable method. It was found after much experimenting that a spark test was the most satisfactory.

For the testing of high speed steel scrap, assuming that it is free from the metals or soft steel parts referred to, it is necessary to have a soft free cutting alundum or corundum wheel running dry, at a speed given by the maker, and located in a dark place so that sparks may show to the best advantage. The spark test is based on the fact that each separate grade of high speed steel develops a characteristic spark by which it can be identified under these conditions. To conduct this test the operator should take samples of steels of known quality and thoroughly familiarize himself with the different sparks shown by them when in contact with the wheel. The color, shape and length of the spark stream should be carefully noted. These sparks will show a dull red stream 6 to 20 in. from the point of contact with the wheel, at which point there is an explosion or opening up of the spark stream. Some high speed steels show a bright star effect, while others break up into lines similar to but brighter than the line running down from the point of contact. Experts can pick out most of the various standard makes by the difference in sparks. This can only be done, however, by experts who have made this a deep study and who are continually in practice.

Take, for instance, the old-fashioned mushet type of self-hardening steel. This throws off a spark very similar to high speed steel with a stream that has a slight tendency to open up at the end but not into what might be termed an explosion. It is interesting to try the spark test on ordinary gray iron, as this resembles very nearly the spark of the old-fashioned mushet steel. It is not unusual, in fact, to receive gray iron on the assumption by the sender that it was tungsten steel.

The American self-hardening steel shows a brighter spark stream and a still brighter explosion than the mushet steel, and can be distinguished from high speed steel by the length of the spark stream and the difference in the color and size of the spark or explosion at the end of the stream.

The molybdenum self-hardening steel, a great deal of which was placed on the market just previous to the advent of high speed steel, shows a spark much brighter than high speed steel but of a character peculiar to itself — not having the brighter scintillating spark of carbon steel, but ending in a long stringy, comet-like explosion at the end of the spark stream.

There are several grades of self-hardening steels made for wood cutting, nail dies, etc. These all show a lighter spark, being low in chromium and tungsten. Then follows the double special or finishing steel, which shows a considerably brighter spark and a lighter red stream. There are some one and two per cent tungsten steels for tools on the market.

Any type of simple steel, such as tool steel or any ordinary soft steel of whatever character or shape, as well as nickel steel, can easily be recognized by a bright spark stream and brilliant scintillating spark explosion.

SQUARING THE FRAMES OF FRENCH LOCOMOTIVES

Special Gages Aid in Squaring the Locomotive Frames and Lining the Driving Box Shoes and Wedges

BY MAJOR C. E. LESTER

Formerly Gen. Supt., 19th Grand Division, A. E. F.

IN overhauling French locomotives at Nevers shop, France, it was customary to remove the boilers and cylinders from the frames and, after stripping off all braces, lugs, shoes, etc., to give the frames a thorough cleaning and careful inspection for defects. A view of a pair of cylinders and frames just unwheeled is shown in Fig. 1. Frequently the frames were sent to the smith shop for repairs, and in their reapplication or in the application of new ones, the squaring gage, Fig. 2, was used. The purpose of this gage was to assist in squaring the frames with the cylinders and with each other, and to check for frame distortions.

It may be explained that frames on the smaller French locomotives are of the slab type about $1\frac{1}{2}$ in. thick and the driving box shoes are bolted to the frame jaws by a suitable number of taper bolts as indicated in Fig. 3. The driving box wedges are provided with tongues which fit into

Fig. 1. French Locomotive Cylinders and Frames Just After Being Unwheeled

corresponding grooves in the female shoes, the latter also being bolted firmly to the frame jaws. The above arrangement of the shoe and wedge also is shown in Fig. 3.

When a locomotive was ready to be reassembled, the frames were bolted to the cylinders and the braces bolted up. The cylinders and frames were adjusted by means of jacks until level, as indicated by the spirit level. A string passed from the center of the cylinder to the rear of the frame was adjusted until exactly in the prolongation of the center line of the cylinder, and any offset in the frame could be detected by measuring the distance between the frame and the string. If there was a slight offset at the rear, due to a bend in the frame, the frame was left alone and bent back into position after putting the boiler in place. Reference to Fig. 4 shows blocks of wood placed midway in the jaws, which acted as a rest for the squaring gage (Fig. 2). The latter was placed so that the gage arm could swing on the outside, the gage beam extending through the frame from jaw to jaw. The sleeve shown was slipped on over the gage beam and held in place by a set screw. With the sleeve held against the

frame jaw, the gage could not slide back in adjusting the set screw.

To square the frames the set screw was adjusted until, with the gage arm swinging, the end of the screw just touched the string. After being adjusted for the back jaw, the gage was moved to the main or front jaw without changing the screw. The gage arm was swung, and if the screw touched the string no adjustment of the frames at that point

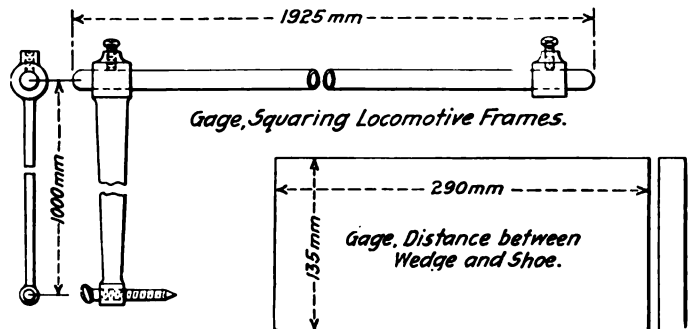

Fig. 2. Gages Used in Lining and Squaring Frames

was necessary. If, however, the screw did not touch the string it was necessary to move the frame one way or the other or to shift the cylinder by means of jacks. Occasionally, with new cylinders it was necessary to remove them and have a little planed off.

After using the gage on one side of the frame it was applied to the opposite side in the same manner as described above. The frames were adjusted until, without changing the screw adjustment, its point just touched the string when

Fig. 3. Shoe and Wedge Arrangement

the gage was used on either side of the frames or at any pair of jaws. With this condition fulfilled, the frames were considered square. The spirit level was again tried, to be sure that the cylinders as well as the frames were level and had not shifted.

Driving Box Shoes

Before bolting on a driving box it was necessary to have the correct distance between the wedge and the shoe. This

distance was obtained by means of a rectangular gage, illustrated in Fig. 2. The gage shown was used for the 4,000 class locomotives and other gages of a similar type were provided for the other classes. When the wedge had been fitted to the female shoe, the rectangular gage was placed against the wedge and a distance of 40 mm. equal to the shoe width measured in excess of the 290 mm., representing the driving box width. This indicated the proper position in which to bolt the shoe.

When the shoes had been bolted to the frame, the straight

Fig. 4. Plan and Elevation of French Locomotive Frames Showing Application of Squaring Gage

edge, as shown at the left in Fig. 4, was placed so that it fitted over the shoes and checked the distance between frames. Three trams were used to obtain the correct distance between the jaws; back to intermediate; intermediate to main and main to front. With the frames carefully squared by the above method and the shoes and wedges lined there was no difficulty in wheeling the locomotives and applying the rods.

CARE AND USE OF PNEUMATIC TOOLS

BY H. S. COVEY

There are four indispensable things required in the successful operation of the air tool, and these are dry air, volume, uniform pressure and lubrication. Dry air may be had by piping the receiving tank in the following manner: The tank should be large, set in a vertical position and provided with a draincock at the outside near the bottom. The large shop pipe should enter the tank from the outside at a point 12 in. from the bottom. When the air reaches the tank from the compressor it is exceedingly hot and has a pressure of seven to eight atmospheres; being hot, it immediately rises to the top of the tank, as does each succeeding pulsation. The air being tapped in the tank, it must remain there until sufficiently cooled. As condensation starts at once, the water falls to the bottom of the tank. As the air cools and drains, it moves downward until it finally reaches the mouth of the shop pipe and moves on its journey to the air tool in good working condition.

Volume and Pressure.—To maintain adequate volume and uniform pressure, the shop mains should be large, as they are the trunk lines which carry the air to the most distant point of the system; they should have a gradual rise until when they reach the most distant point they are considerably higher than the receiving tank. All branch lines which cross the path of the main trunk line, from which they draw their supply, should always pass above and take their air from the top of the main pipe. If there is any water still in the mains, it is at the bottom working its way back to the supply tank.

Compressed air is saturated with oil from the compressor and is never quite eliminated at the receiving tank where the first cooling of the air takes place, as previously mentioned. A considerable proportion of the oil, therefore, passes on through the shop mains and branches to the drop pipes, at

which point the hose line is attached, leading directly to the air tool.

The oil has a detrimental effect on the rubber inner tube of the hose, causing it to disintegrate, particles of which become detached and enter the air tool, where they lodge in the valves and air ports of the hammer, causing serious trouble and inefficiency.

Oil and Water Separator.—Inventive minds working on this problem have recently discovered a simple device which we believe to be a solution of the trouble. This is an oil and water separator that may be made in your own shop at a nominal cost. It consists of a 3-ft. section of 5-in. iron pipe, capped at top and bottom, and is attached to the branch air pipe lines which feed the drop pipes and hose lines. The branch pipe enters the separator at the top through one side of the cap and runs down the inner side of the separator to a point three inches from the bottom when the air is liberated, escaping into the cylinder and returning to the top of the cylinder through a series of baffle plates which are attached at regular intervals to the branch pipe; this filters the air and the oil clings to the baffle plates.

The air leaves the separator at the top, entering the branch outlet pipe attached to the cap at the opposite side to the inlet. The air is thus freed from oil and such water as may still remain in the system.

The separator is drained of its accumulated water and oil through the drain cock provided at the bottom cap of the separator. Occasionally the lower cap of the separator should be removed and the baffle plates cleaned by means of a stream of compressed air which quickly removes the oil adhering to them.

Fittings.—The selection of proper fittings that will offer the least resistance to the passage of the air is just as important as large pipe lines to aid in the reduction of friction in transmission of the air from the drop lines through the hose to the air tool. Air valves which have any angle turns in the air passage are objectionable, because they impede the direct travel of the air into the hose. Hose couplings, like the valve, should have an unobstructed air passage.

Lubrication.—The close fit of all working parts of the air tool necessitates frequent lubrication, particularly in the riveting and chipping hammers. The oil used should be of good quality that will not gum; heavy black machine oil should never be used, as there are numerous air ports in valve blocks and cylinders that must be kept open. The tendency of the heavy oil is to clog these ports, which impedes the proper circulation of the air and reduces the power of the tool.

If the air is charged with water it washes away all lubricant and the hammer loses its efficiency, refuses to work, and the delicate parts and polished surfaces become rusted. The hammer should have a bath every night in coal oil, which soaks up the worn-out oil of the day, and each morning should be attached to the hose and blown out thoroughly, then fresh oiled and put in service. If treated in this fashion it will perform like a new tool.

MORE EQUIPMENT NEEDED.—Industry continues to be hampered by inefficient transportation. This is not a condition which can be materially aided by redistribution of cars, but can be remedied only by the purchase of a large amount of new equipment and the heavy repairing of old. Although a number of railroads are now in the market for rails, cars and locomotives, the buying movement has not yet reached large proportions. Extensive purchases on the part of the roads must wait the making of adequate financial plans. Some needs, however, such as the requirements of the repair shops, are so urgent that buying of this kind cannot long be postponed.—*National Bank of Commerce in New York.*

HOW ENLOE STRAIGHTENED OUT WESTDALE*

The S. M. P. Thought Berry Was "Falling Down." A Visit to the Terminal Showed Why Engines Were Delayed

BY FRANK EDWARDS

THINGS were not going well at the Westdale roundhouse and hadn't been for more than a year. Westdale was the most important terminal on the Valley Division of the Central and was hard to handle even under ordinary conditions. With the unusually heavy business, which had kept up the entire year following the war, had come a dearth of competent mechanics. The combination had changed the division's standing from one of the best on the system to one of the worst. If a day went by without an

for some time. I have about decided that Berry isn't heavy enough for the job."

"How is he fixed for men?" asked the general manager.

"Why, he has more men than I ever had," replied Enloe. "Business is some heavier but I consider that he is well fixed for men. He doesn't seem to be able to handle them right. I'll investigate this delay to number eight and let you know what I find. I've about made up my mind to go over there and stay till I get that place straightened out if it takes a month."

"That might be a good idea," said the general manager, "for we are having nearly every meat train delayed there for power and then when they do furnish an engine it is usually late and frequently loses time over the division."

Other matters were then discussed but for the remainder of the day Enloe was not able to get his mind off conditions at Westdale and the delay to number eight. He knew that Gridley did not have time to make a long stay over there yet he was convinced that either himself or Gridley would

Enloe Delighted in Recounting Some of the Rush Jobs He Did

engine failure, two would occur next day and Roundhouse Foreman Berry was in despair.

Charley Berry had been made on the division and until recently had been considered a coming mechanical department official. He was just in his prime, was well liked by all the men, and was a thorough mechanic, yet the engine failures and delays were increasing monthly. Master Mechanic Gridley and Mechanical Superintendent Enloe were beginning to doubt the wisdom of leaving him longer in charge of the Westdale roundhouse. Berry had tried many times to make them see that he was handling the work to the best advantage and that all his trouble was due to the large increase in business with an actual decrease in the force, and this force only turning out about half the work it did before the war.

Enloe had made his reputation as foreman at Westdale and ever delighted in recounting to Gridley and Berry some of the rush jobs he did when he was running Westdale. Gridley had first made good on about the same kind of a job on another division and both were inclined to feel that what they could do in the good old days Berry could do now if he would just organize his force right, although neither of them could pick any definite flaws in Berry's methods.

As Enloe was leaving his office on day to go to lunch he met the general manager, who promptly said, "Enloe, I just came in on number eight. We had a 30 minute delay at Westdale on account of the engine being late and then lost 40 minutes from there in with the regular train. They tried three engines before they got one ready and it wouldn't steam. What is wrong over there, anyway?"

Enloe replied, "Things haven't been going right over there

"Hansen, What Took You So Long On That Rod Brass"

have to go and stay for a while in order to get Berry lined up.

Next morning when Enloe reached his office he found Gridley waiting for him.

"I have just received a wire from Berry," said Gridley, "he fell off of number ten's engine last night and broke his right arm. The doctor is sending him to the hospital this morning and claims he will be gone three or four weeks at least. I'll go over on number nine this morning and get someone broken in on the job."

"Who have you got over there to handle the work when Berry is off?" asked Enloe.

"Well, we haven't anyone just now," replied Gridley.

*Entered in the *Railway Mechanical Engineer's Prize Story Contest.*

"You know Berry wanted our permission to break someone in on his job last time we were over there but we decided it wasn't necessary and we didn't want him to take a man out of the gang just then. Lane and Smith both used to be able to handle that place in emergency but they went to the navy yard and never returned. This is going to delay all the work we had planned on this end for a week or two unless you can arrange to oversee it yourself. I'll probably be over there a week or more."

"Now, say," interrupted Enloe, "I just promised the general manager the other day that you would start that work on this end today and that you would personally see it through. I've got things in the office in pretty good shape and I'll go over to Westdale myself and run that place until Berry gets back or at least stay till I get someone lined up that can handle it. I handled it once and I have been wanting a chance to straighten it out again. I know most of the boys down there. A few of them were working when I was running the place and I'll pick out one of them and stay with him until he gets started."

As soon as number nine reached Westdale Enloe hurried to the roundhouse and to his surprise found a young man named Scott in charge. On questioning Scott he learned that Berry, against instructions, had had the foresight to break a man in to protect his place. He soon decided that Scott appeared to be entirely competent.

The first day passed without any bad luck and Enloe spent most of his time looking over the engines in the house and in conversation with some of the oldtimers or consulting with Scott.

When Enloe reached the roundhouse next morning Scott hurried to explain that the 503 had just come in off the Baileyville branch with a front end brass that had to be reduced. "It is nine o'clock now and we just got her in the house," said Scott. "She is due to go back at ten and the chief just told me he wouldn't stand for any setback this morning as they had some stock to pick up going back. We haven't got another engine here we can use."

"We can make that all right, Scott," returned Enloe. "Let Hansen have the job. He has reduced a brass like that for me in 45 minutes many a time. I saw him working on the 816 down there. I'll see him at once and explain what we want."

Enloe found Hansen and said to him, "Hansen, the 503 is just in with a front end brass cut out. I wish you would start on it right away and do your best on it. We want to run her at ten o'clock. You have done the same kind of a job for me many a time in 45 minutes."

"I'll do all I can, Mr. Enloe," replied Hansen.

Enloe felt so sure that Hansen would finish the job on time that he dismissed it from his mind and went over to the car department and watched the work for a while. He returned about 11 o'clock and Scott explained that he had had a 30 minute delay on the 503 due to Hansen not finishing the rod brass in time. When he finished Enloe exclaimed, "Hansen has got to explain to me what took so long on that job. There is no excuse for it."

Enloe at once found Hansen and began, "Hansen, what took you so long on that brass? I've seen the day when you could have done that job in 30 minutes."

"Mr. Enloe," replied Hansen, "I am just as fast as I ever was but we don't work like we used to work. When you were here, I would have taken that brass down, reduced it with a hammer and chisel and file, hurried over to the shop and cut a liner myself and as you say I would have been done in about 30 minutes. Nowadays I can't reduce a brass myself for you have agreed with the shop committee that it is a machine job so I had to take it to the machine shop and wait for it to be done on the lathe. He had a rush job in the chuck and that delayed me 25 minutes. Then I had to hunt up a boiler-maker to get a liner cut as your agree-

ment with the boiler-makers won't permit me to cut a liner. It took me ten minutes to find him and get the liner cut. I hope that makes it plain to you why I did not finish the job as soon as you expected."

"It does," said Enloe as he walked away.

This incident gave Enloe enough to think about for the rest of the day, and he began partially to understand why Berry was not able to turn out the work as he used to. In the afternoon when Scott found a moment's leisure he said to Enloe, "Mr. Enloe the 822 will be in on number seven tomorrow morning and we have got to change her tires. She lays here 20 hours and I'll try to change them during her layover as we haven't got an extra engine just now. She is due to go back on number eight at five o'clock next morning but if we don't finish her we can double number eleven's engine back."

"There is no reason why you can't get the tires changed and get her out in her turn," replied Enloe. "I have seen

He Found Carlson and His Helper Sitting On Their Tool Boxes

Carlson change tires on that class engine more than once and have her ready to go in 12 hours. Better put him on the job and let him stay till he finishes it."

"I'll arrange to do that," said Scott.

Enloe was on hand early next morning determined to see that there was no delay in starting on the tires. He made it plain to the hostlers that he wanted the 822 hurried in the house but it was after ten o'clock before they could get the big Pacific type engine across the pit and in the house. Enloe and Scott both explained to Carlson that they expected him to change the tires on her and get her ready for number eight in the morning.

Carlson merely said, "I'll do all I can."

When Enloe started for lunch just before noon Carlson had all the rods off and was ready to jack her up. When he returned about one o'clock he found Carlson and his helper sitting on their tool box watching four laborers jacking up the engine. These men were working half-heartedly and it took but a glance to see that they were inexperienced, thoughtless and making about one fourth the progress that two good energetic men could make. On seeing Enloe Carlson got up and remarked:

"We are all ready to go, Mr. Enloe, as soon as the boys get her jacked up. I've got everything ready."

"Those fellows aren't making any headway," replied Enloe. "Why aren't you and your helper working with them? I've seen you and one helper jack up an engine like that in half the time they are doing it."

"We can't do it, Mr. Enloe," returned Carlson. "You see our shop agreement says that the mechanics and helpers will be relieved of all heavy jacking when there is a labor gang working. Scott can't spare any more of them just now."

Enloe saw green for a moment, then turned and walked away thinking of the many times he had seen Carlson in action on just such a job and how impatient the same man used to become when someone did not appear to be working fast enough and how he seemed to brush every obstacle aside in his efforts to get a job done on time.

At four o'clock, which was the quitting time for the day shift, Carlson had one tire off and was heating another. Enloe had expected him to have all six tires off by four.

Scott was well aware that Enloe was not satisfied with the time Carlson was making on the tires and for that reason hesitated about explaining that owing to the agreement he could not hold Carlson overtime on the job. Finally just at four o'clock he found Enloe and explained the situation to him.

"Mr. Enloe, we can't work Carlson overtime on that job as he has already had more than his share this week and the committee has notified me that it is James' time to work. I tried to explain to them that Carlson was the best man on tires and that we just had to have the engine for number eight but they took the position that it wasn't the machinist's fault and the company didn't have another engine here to protect their train and that the agreement was made to live up to."

"What kind of a man is James?" inquired Enloe. "I don't know him."

"He is all right," replied Scott, "on some kinds of work and can set tires but he won't make half the time that Carlson would make but we will have to use him or let the job wait."

"Go ahead and use him," said Enloe. "I can see now that you won't get her finished in time for number eight but you can double number eleven's engine back as you suggested. I believe I'll go on down to the hotel. You seem to be doing all I could expect of you, on this job, and I'll go in on number eight in the morning."

Enloe sat late in his room that night. He was thinking of the many new problems that confronted the present day roundhouse foreman and at last he could understand why hardworking Berry—hardworking with head as well as muscle—was unable to get the work done that he himself used to get done with the same size gang. He thought of the many times Berry had tried to explain all this to him and how he had refused to believe. He also came to understand why the engines' failures on his district were more numerous than on any other district of the system and that his success in holding his payroll down had cost him the high standing of his district. It was plain to him at last that labor conditions had changed greatly since he was a roundhouse foreman.

Next morning the engine for number eight was 35 minutes late. James didn't get the tires finished in time and number eleven's engine reached Westdale with a broken spring hanger. The night foreman had no other engine so had to make repairs and this caused the delay. As usual, Scott sent a statement to Enloe and Gridley explaining the delay and in this case Enloe did not close it out by saying the delay was evidently due to the poor judgment of the foreman.

It will probably never be known just what explanation Enloe made to the general manager but before Berry returned from the hospital the force at Westdale and also at the other roundhouses on Enloe's district had been increased 25 per cent. Three months later the Valley Division had again become the best division on the road, all due to Enloe lining up Westdale.

INFLAMMABLE AND EXPLOSIVE LIQUIDS IN SHOPS*

Railroad shops, especially large ones, are usually closely grouped for economy in operation, and often the congestion is such, that it renders a large proportion of the property subject to loss from one fire. Many shop properties have been added to from time to time, without much thought as to segregation of hazardous processes. This risk is increased by the fact that locomotives move in and about the shops, thus making a spark hazard. Extreme care should be applied to safeguarding the hazards, especially in the use of inflammable or explosive materials; otherwise quick spread of fire and heavy losses are not improbable.

The inflammable liquids used in railroad shops are gasoline, benzine, paint and varnish, oils, wood alcohol, paint and varnish remover and lacquers.

Gasoline

Where the main stock of gasoline or benzine exceeds 50 gal., it should be stored in underground metal tanks installed in accordance with approved regulations. Where the main supply does not exceed 50 gal., a steel drum of 50-gal. capacity with a metal faucet is a satisfactory storage container. This drum can be kept in a small, well detached metal enclosure that is kept locked and is conspicuously marked "Keep Lights and Fires Away." Where not over five gallons constitute the main supply, an approved safety can may be used. This can should be kept in a cool place. For transferring gasoline from the storage tank or drum to the point at which it is to be used, only approved safety cans should be used. These safety cans preferably should not exceed one gallon in capacity, and should be smaller if a smaller amount than one gallon is sufficient for a day's supply at any point.

In cleaning triple valves, some shops use gasoline while others use kerosene with apparently satisfactory results. Where gasoline is used it should preferably be placed in substantially constructed galvanized iron cans of as small size as practicable for the purpose. These cans should be mounted on the work tables, so that their tops are almost flush with the surface of the table, and should have a drain valve at the lowest point of the bottom. Cans should be provided with hinged covers which normally will be shut to prevent evaporation of the gasoline. Gasoline remaining in these cans should be removed through the draining valve at the close of each day. This cleaning work should be conducted at a point remote from open fires, lights or flame, and only approved electric light fixtures should be permitted.

In cleaning electric generator and motor parts with gasoline, similar precautions should be taken as in cleaning triple valves, except that more gasoline and larger cans must be used in the latter process owing to the size of the parts handled. The form of can should be of such proportions as not to be upset easily, as they are usually handled on the floor. They should be provided with hinged covers and with substantial handles, and the liquid contents should be removed from the cans and stored outside the building at the close of each working day.

Gasoline is sometimes required for removing grease and oil from upholstery and furniture. The gasoline for this purpose should not be kept in or around the shops in glass bottles or in open cans or buckets; but in a small standard safety can. When using gasoline for dry cleaning, it is recommended that the material to be cleaned be taken out doors when practicable. In cleaning cloth surfaces with gasoline, the mere friction of the cloth saturated with gasoline upon another surface is sometimes sufficient to produce

*From the report of a committee presented at the sixth annual meeting of the Railway Fire Prevention Association, held at Chicago, November 18-20, 1919.

static electric sparks, which may ignite the vapor. Fires sometimes thus occur in dry cleaning processes, in spite of every precaution in avoiding the proximity of open lights or fires.

Gasoline is used in small blow torches or plumbers torches for soldering in electrical repair shops and also for burning off paint. In some shops kerosene is used for the same purpose and naturally involves a much less fire hazard. Where gasoline torches are used they should be kept in a fire proof cabinet, preferably located outside, when not in use. They should be filled from a standard safety can, and this filling preferably should be done out of doors. The torches should be inspected frequently to insure that they are in good mechanical condition. Fires are frequently caused by workmen going away and leaving burning gasoline torches. The torch may be upset or moved so that the flame comes in contact with some combustible material.

It is of course important in using gasoline or kerosene torches for burning off paint, that they are not used at any place where varnish removing compounds are employed. In some shops large gasoline pressure tanks are used inside main buildings, and the gas produced is used in connection with blow torches for paint removing. Such practice is very hazardous and should not be permitted. These tanks should be in an underground pit, well detached from buildings, and an approved system of piping and connections should be provided.

Where tire removing is done with the use of gasoline fuel, the process should be conducted out of doors, and at a safe distance from buildings. Fuel oil and kerosene are both successfully used for this purpose at some points, and are safer than gasolines.

Paints and Varnishes

Paints and varnishes used in railroad shops are not generally highly inflammable, but are combustible, and are usually kept in quantity. They should be stored if practicable in a separate building of fire resistive construction, located a sufficient distance from other shop buildings to eliminate the danger of exposure. Paints and varnishes should be stored in sheet iron drums provided with valves for drawing off the liquid. Metal pans or troughs should be placed under the valves to catch any drips. Standard metal waste cans with self closing lids, should be provided for the reception of waste, or cloth contaminated with paint, oil or varnish. This material should be removed from the cans at the close of each day, and burned or otherwise safely disposed of.

In case any paint, oil or varnish is spilled, it should not be absorbed by sawdust, or similar material; sand should be used for this purpose.

The paint storehouse preferably should be of brick, or concrete construction. It is recommended that wire glass set in metal frames be used for window openings, and approved metal covered fire doors for door openings. At the openings between various sections, small two-inch concrete sills should be provided. The building should be heated by steam and lighted by electricity, wired in conduit, with vapor proof globes, and switches installed outside of the building.

Where practicable the oil storage should be a separate building from the paint and varnish storage. When housed in the same building a distinct sub-division should be provided between the two occupancies by a standard brick fire wall, with door openings protected by a standard fire door on each side of the opening. Oil houses should be divided into two distinct rooms; the waste room, and the main oil dispensing room. Sometimes a third room is necessary for filled barrels, where no basement is provided. The construction, lighting and heating of the oil house should be similar to that recommended for the paint and varnish storage.

The most common form of fire protection for paint, varnish and oil houses, is the steam fire extinguishing line, by which steam is introduced into the building. These lines are controlled by manually operated valves located on the outside of the building. The effectiveness of this method of fire extinguishment is dependent on the complete confinement of the steam. In order to prevent its escape, all window openings should be equipped with wired glass in metal frames, the windows to be counterbalanced to close with the melting of fusible links. If there are ventilators in the roof they should also be equipped with shutters with fusible links. Chemical fire extinguishers, and a liberal supply of sand pails should be provided. On the outside of the building a sign should be posted reading, "Keep Lights and Fires Away."

Empty and filled oil barrels or drums should be stored at as safe a distance as practicable from the oil house, and as an added precaution, protected from sparks by a noncombustible shelter. All empty barrels or drums should be tightly closed.

Paint and Varnish Remover

Paint and varnish removing compound is usually a highly inflammable liquid containing acetone, benzol, etc. It is commonly shipped to the shops in wooden barrels, which are stored outdoors until used. These barrels are not always in good condition when received, hence they should be inspected when received to see that leakage and fire risks do not occur. When paint and varnish remover are being applied to cars, these cars should be outside of and at a reasonable distance from any building. During this process no fires, lights, blow torches, etc., should be brought in the vicinity of the car.

In removing paint and varnish from small pieces, it is at times necessary to work indoors. A small detached building should be used for this purpose. This building, if not of fire resistive construction, should have all combustible parts covered with sheet iron. When dipping tanks are used for the varnish remover, these tanks should be kept covered except when objects are being placed in or removed from the tank. Not more than one barrel of the varnish remover should be kept in the building or compartment in which varnish removing work is done. Care must be taken that any liquid which has spilled or leaked is at once removed. The building should be well ventilated, and if lighted artificially, vapor proof electric lights with wiring in metal or other conduits must be used.

Metal Lacquers and Enamels

Lacquers and enamels for metals consist essentially of nitro-cellulose in amyl acetate solution, with or without other ingredients. Lacquers and enamels are commonly shipped by the manufacturers to the consumer in boxed cans of not over five gallons capacity. They are commonly kept in these shipping containers until used. Lacquers and enamels are usually applied either by dipping or spraying. When applied by dipping, the dip tanks should have approved covers, and these covers should be kept closed except when articles are being dipped or removed.

Where lacquers or enamels are applied by spraying, the work should be done where there is good ventilation. Ventilators, work tables, or other objects which are in the path of the spray, gradually acquire a coating of non-volatile residues from the lacquers. This residue consists, in large part, of dry nitro-cellulose mixed with gums, pigments, etc. This mixture is extremely inflammable, and if ignited in any quantity will make a very hot fire and one difficult to extinguish. These solid residues should not be allowed to accumulate, but should be scraped up, removed, and burned at frequent intervals. Drip boards should be of non-combustible material.

THE HUMP METHOD FOR HEAT TREATING TOOLS

The Critical Point of the Steel Being Treated Is Used to Determine the Proper Time for Quenching

ONE of the latest developments in heat treatment is the so-called hump method which has been developed by the Leeds & Northrup Company, Philadelphia, Pa. The method makes use of a recording pyrometer to determine when the steel being heated reaches the critical temperature, and takes its name from the fact that an offset or hump occurs in the heating curve at the transformation point. Heat treating by the hump method has been applied successfully to the

Fig. 1. Furnace Arranged for Heat Treating by the Hump Method

treatment of gears, taps, drills, punches, dies and other types of tools.

The usual practice when using this method is to heat the parts in an electric furnace of the type shown in Fig. 1. The tool is suspended by means of a small wire from the tool support in such a manner that it rests upon or is in close prox-

Fig. 2. Electric Circuit Connections for Controlling Rate of Heating

imity to the base metal thermocouple. The top and bottom of the furnace are made sufficiently tight to prevent any amount of fresh air to enter, so that the atmosphere is practically neutral at all times. In applying the methods to production work, the parts to be treated are placed upon suitable holders, and these are placed into the furnace, so that the work surrounds the thermocouple.

A rheostat is connected in series with the furnace winding,

as in Fig. 2, by means of which the rate of heating of the furnace may be changed at will.

The thermocouple is connected to a curve drawing potentiometer recorder which gives a graphic record of the temperature of the hot junction of the thermocouple, but not the temperature of the work, at all times. The potentiometer recorder provides the maximum sensitiveness, and therefore enables the operator to note quickly a sudden change in the temperature of the hot junction of the thermocouple. A sample curve, showing the record of the temperature at all times while hardening a blanking die, is shown in Fig. 3.

Before the work is placed in the furnace the temperature of the latter is brought up to about 1,400 deg. F., as indicated by the thermocouple and as shown at point A on the temperature curve. The tool is then suspended in the furnace, the cover replaced and the control switch opened. Thus the energy input to the furnace ceases and the tool is allowed to slowly reach the temperature of the furnace or nearly so. In the meantime the temperature of the furnace walls will drop, as shown by the upper dotted curve. The thermocouple temperature drops rather suddenly when the cold tool is placed upon it, but soon regains some of its heat as the tool begins to rise in temperature. The rise in the temperature of the tool is shown by the lower dotted curve. When a sufficient length of time has elapsed all these bodies have reached

Fig. 3. Curve Showing Temperature Changes in the Furnace and in the Tool

approximately the same temperature, as shown at point B on the curve.

This means that all sections of the tool are at the same temperature, or in other words, the tool has reached a uniform temperature throughout.

At this time the energy is applied to the furnace and the current adjusted by means of the rheostat to a value just great enough to increase the temperature difference within the body of the tool at any time, and when the steel reaches its decalcescence point all sections of the tool will be at approximately the same temperature. When the decalcescence point or critical point is reached the carbide passes into solution in the iron (see *Railway Mechanical Engineer*, April, 1920, page 236). This change causes an absorption of heat without a change in the temperature of the steel.

Consequently the increase in temperature of the thermo-

couple is affected, as shown by the abrupt change in the slope of the curve at *C*. In fact, the thermocouple behaves just as if it had gone through a critical point. When the transformation is completed, there is another change in the rate of heating of the thermocouple, as indicated at *D*. The temperature of the tool is then allowed to increase for a sufficient time beyond this point to insure hardness and quenched, as shown at the point *E*. The time allowed above the "hump" depends upon the nature of the quenching medium as well as the mass and shape of the tool as is the case in any method of hardening.

The "hump" on the curve is used as a reference point, and by its use a number of the variables which occur in present methods of heating are controlled.

In order to properly heat treat a punch or die it is necessary to control the following variable conditions:

1. The amount of increase in temperature of the tool above its decalescence or critical point before quenching. A variation in this quenching point will result in a tool being soft when it is removed from the quenching medium, or will result in abnormal growth of grain size, causing the tool to be weak and very poor as regards physical properties.

2. The uniform rate of heating of the tool, too fast heating resulting in breakage, deformation or in setting up stresses which will cause an early failure in service. Too slow heating has been found to cause a volume change in the steel which results in a very appreciable increase in the cost of finishing the tool.

3. The atmosphere in which the tool is heated. An oxidizing atmosphere results in a decarbonized surface which decreases the efficiency of the tool enormously.

4. The quenching conditions. These, from present knowledge, seem to be more under control than the heating conditions.

The use of the electric furnace and the hump method of heat treatment provide a means of controlling these variables and enable the operator to repeat or change the heating conditions at will. It does not depend upon the accuracy of the pyrometer but upon its ability to show the time of the transformation.

The gas furnace and present "soaking" method of heat treatment do not allow a control of the quenching temperature because they depend upon the accuracy of the pyrometer, upon the operator's eye to judge the difference in temperature of the thermocouple and work, and also upon the assumption that the critical point of the steel in the furnace is the same temperature as the critical point of the sample, from which determinations were made in the beginning.

The use of the lead pot or salt bath eliminates to a certain extent the error caused by the difference between the temperatures of the work and furnace, but has the disadvantage over the gas furnace of too rapid heating with practically no control of the rate of heating.

The atmosphere is hard to control in the gas or oil furnace, and while decarbonization is not serious by the use of the lead pot, we are presented with the additional problem of keeping the tool free from lead spots by its use.

By the use of the hump method of heat treatment the steel is quenched at the proper temperature as measured from the critical point of the tool itself, and not of a sample of the steel. This makes it possible to control the grain size and physical properties and to repeat the results at any time.

The uniformity of heating and control of the rate of heating eliminates the breakage, distortion and volume change which are present where there is no control over these conditions.

Comparative tests were conducted on taps hardened in the electric furnace by the hump method. Because of the fact that there was very little volume change, and therefore very little lapping necessary on the taps, the hard outer surface of

the tool was left intact, and in every case the electric furnace treated tools have shown a gain of from 25 to 50 per cent. In every case except one the gain was obtained before the first regrinding, showing the maximum work obtained from those taps was before the outer hard surface was removed.

There is no inherent reason why this method cannot be applied with gas furnaces, but up to the present time it has not been found possible to control the gas to secure a uniform rate of heating. A change in the quality of the gas or the pressure will cause a hump on the curve, which will not be the critical point of the steel.

It is necessary to have all tools in one heat of the same steel or of steels having the same critical temperature. The weight of steel in the charge must also be sufficient to insure a decided hump. A relatively small charge is sufficient, however. The curve shown in Fig. 3 was taken from a furnace 8½ in. in diameter by 14 in. deep when heating a carbon steel die weighing about two pounds.

The use of the hump method of heat treatment by no means eliminates all of the problems in hardening, but it makes it possible for the hardener to reproduce or change his hardening conditions at will and enables him to gain much valuable experience and knowledge that is now lost simply because conditions cannot be controlled or repeated.

THE CARELESS MACHINIST'S CREED AND HIS REASONS

- 1st. I believe in using a monkey wrench in preference to a hammer, because a monkey wrench looks better when it is all battered up, and besides that is what it was made for.

- 2nd. I believe in borrowing other men's tools in preference to buying some of my own. This is a good method of cutting down the high cost of living and saves me carting around a heavy tool chest in my travels.

- 3rd. I believe in oiling my machine once every six months at least. This is a great saving to the company, as oil costs something these days.

- 4th. I believe in keeping the shop tools in a heap on the floor instead of using the locker provided for this purpose. In this way they can have their cutting edges ruined far more quickly than by using them on the work.

- 5th. I believe wiping off chips with my fingers in preference to using a stock or brush provided by the company, because the former is a most ancient custom and takes the place of a surgical operation.

- 6th. I believe in keeping tools under the planing machine table and in reaching for them while the table is running. This breaks the monotony of life and gives opportunity for some clever gymnastics.

- 7th. I believe, when running my shaping machine, in having my slide rest projecting far enough to hit the bed on the back stroke. This is great fun and provides employment for the repair gang who might otherwise be out of a job.

- 8th. I believe in wearing loose or torn overalls and a long flowing necktie when running a high speed lathe or drilling machine. This is also a very ancient custom and a suitable dress for machine-shop work.

- 9th. I believe in mixing brass, babbitt, steel, and iron chips in the pans. This mixture always looks well and proves fascinating employment to the man who has to separate them.

- 10th. I believe in using a long-handled wrench in tightening a three-quarter bolt and much prefer a half-nut to a nut on the whole depth. This ruins the bolt at once instead of prolonging its life indefinitely.

- 11th. I believe in blaming the night man when anything is lost or goes wrong with my machine. He is not here to contradict me, so I can explain it all to the boss satisfactorily.

- 12th. Finally, I believe in abiding by all the rules and regulations of the company to the best of my ability when the boss is around.—By *N. O. Good in Deane News*.

A MEASUREMENT RECORD FOR RAILROAD SHOPS

Tabulation of Dimensions of Parts Eliminates Errors and Delays in Making Repairs to Locomotives

BY H. L. BURRHUS

THE taking and recording of accurate measurements is essential in shop work in order to eliminate delays and errors in supplying repair parts for locomotives. In a roundhouse located at a considerable distance from the general repair shop there frequently is a long delay in getting parts because the proper dimensions are not known until the part is actually needed, and often in transmitting such information to the general shops errors are made which entail loss of time and confusion at both points. Much of this trouble can be avoided by utilizing information that is available in every shop.

A system of charts on which measurements of parts may be recorded will facilitate the handling of such work, particularly at outlying points having meagre shop facilities. This system may be called a "calibration system," although not strictly within the ordinary meaning of the term. Such a system is described in this article and typical charts are shown in the drawings.

When general repairs have been completed in the back shop it has been customary to destroy the record of measurements which were secured to make repairs to the various parts. For instance, driving box lateral was figured out on a slip of paper and handed to the driving box foreman. After the engine was wheeled, lateral checked and found to be correct there was no further use for that particular record, and it was thrown away so that it would not be mistaken for that of some other locomotive.

The mechanic who bores driving boxes will caliper the journals, list the sizes on a slip of paper and bore the set of boxes. As soon as the boxes are applied and found to be correct, this mechanic will destroy his record of sizes to avoid any confusion.

Cylinders are calipered for piston heads, and after the heads are applied, the measurements are soon forgotten. The shoe and wedge mechanic will caliper a set of driving boxes to secure sizes for laying out a set of shoes and wedges. After the engine is trammed he will destroy the list of box sizes. Months after the engine has left the shop and is working at a distant terminal, some piece is broken or worn out and a replacement is required on short notice, but, because no authentic record of sizes is available, long delay ensues.

Any one who has been responsible for roundhouse operation realizes the serious delay and errors encountered in trying to transmit by telegraph sizes to cover a needed part. All too frequently in the haste to send a message, some important dimension is overlooked and the back shop is forced to ship out a piece which is only partly machined, depending on the inadequate terminal facilities to finish it ready for application. If the correct information had been received, the back shop could have machined the part ready for immediate application with only a few minutes extra time, but to do the work at the roundhouse may take hours. The roundhouse foreman will often claim that the back shop pays no attention to his requests; on the other hand, the back shop forces will criticise the roundhouse man for not sending complete information. No matter which one is at fault, repairs are held up and congestion soon adds to the already numerous duties of the foreman at the roundhouse. A system of recording important dimensions would prevent this confusion and eliminate any chance of error.

If a right front driving box is required, the general repair

shops will have a complete record of all sizes necessary to prepare an exact duplicate of the box which is to be replaced. Or if it is a piston head, information is at hand so that it will require but a short time to apply it to the engine at the outside terminal.

When driving wheels are removed for general repairs, the journals, crank pins and wheel hubs are calipered to determine if they are worn or out of round. These sizes can be recorded and sent to the office to be transcribed on the master chart and after repairs are completed the finished sizes can be added to the chart. In this way a record of both the original size and the finished size is obtained and the securing of this record has made very little additional work as the checking must be done in order to make the repairs. The data thus secured also give the dimensions required for driving boxes and rods. After the driving

Typical Chart for Wheel Measurements

boxes are completed and the figures showing hub faces and bore are sent to the office, it is possible to record on the master chart all information pertaining to driving boxes and side rods.

Records Are Valuable In Emergency

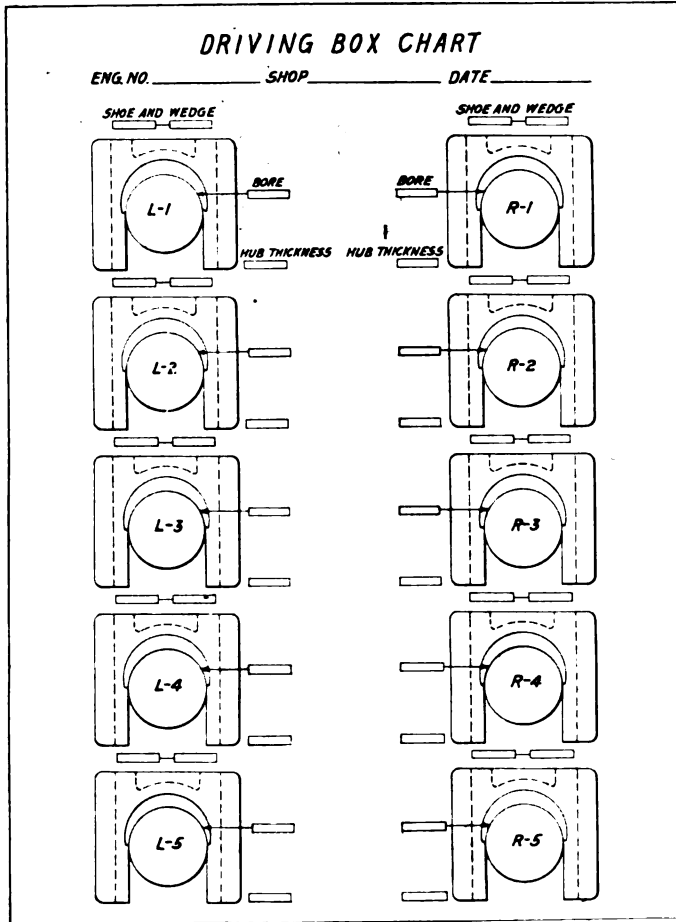

There are some foremen who keep book records of sizes of various parts which are handled by their departments, and for many emergency jobs these records are found in-

valuable. Thus it may be said that this record or calibration system is nothing more than the gathering up and filing of valuable information that is available in every repair shop, but usually is thrown away or lost. A complete and adequate system to maintain records of essential parts can be established without adding to the duties of the supervision. Such records will not only assist in the maintenance of motive power at outside terminal points, but they will help the stores department to secure information on which to base requests for material that ordinarily requires considerable time for delivery.

requirements. While it is practically impossible to obtain accurate measurements with a caliper the micrometer is so finely graduated that pressure fits can be made with a fair degree of accuracy.

How the Charts Will Help

The use of these charts will enable the stores department to order material in advance, thus avoiding delays from that cause. A note forwarded to the stores department to the

Driving Box and Shoe and Wedge Chart

To simplify the recording process, charts are provided so that the terms and location of parts are identical for all shops. The information used in various departments can be assembled at the general foreman's office and tabulated on one master chart. To provide duplicate charts for the use of the shop forces, for the roundhouse or terminals, for filing in the office of the general foreman or the master mechanic and to file at the office of the mechanical superintendent, it is suggested that the charts be compiled on tracing cloth. After all measurements are filled in, blue print copies should be made and distributed.

It will be claimed that no two mechanics "feel" the same with calipers so as to record accurate dimensions. One man may caliper "heavy," while another mechanic has a "light" touch, and the difference between these two workmen's sizes will vary enough to make the record of dimensions of no value. But railway mechanics are fast coming to the use of micrometers, and micrometer measurements do not vary.

Railway work being repair work, it is practically impossible to use snap gages, but the micrometer will meet all re-

Diagram of Cylinder and Valve Dimensions

effect that certain parts had worn to the limit at the time of the last shopping gives ample time to secure new parts.

Let us analyze what this chart means to the outside terminal. A switch engine breaks a driving box. Under ordinary conditions a new box cannot be ordered until the old box is removed, so that necessary measurements can be secured. This causes delay and congestion in the roundhouse. With the calibration system in use a new box can be or-

Chart for Crosshead and Guide Sizes

dered before the engine reaches the roundhouse, and by the time it is stripped the chances are that the new box will be in the shop ready for application.

Analyzing the classes of repairs which confront the outside terminal and cause the greatest amount of congestion, it will be found that they can be properly placed under five general heads as follows: (1) Pistons and valves; (2) cross-heads; (3) driving boxes and wheels; (4) rods; (5) eccentrics and straps.

If every outside terminal carried a stock of material to protect these five classes of repairs, each point would have a storeroom of considerable size. As it is the general practice to carry only sufficient supplies for emergency work at outside terminals the back shop or home terminal is depended on for other requirements. Thus cylinder and valve chamber

packing is one item which usually calls for rush shipments. While it is admitted that the actual sizes of the cylinder or valve chamber should be given, it is possible to prevent the tying up of power by using rings that are the same size as those used when the engine was turned out of the shop. If, however, the chart shows the cylinder size to be $22\frac{3}{4}$ in., though the original size was $22\frac{1}{2}$ in., it is evident that the cylinder has been bored and that the standard rings will not answer. If rings for a $22\frac{3}{4}$ -in. cylinder are furnished and at the time of application the cylinder is found to be $22\frac{7}{8}$ in., the master chart at the home terminal should be corrected to show this dimension.

The main dimensions for a crosshead will be the sizes of the guide bearings. But when one remembers that a crosshead will be shipped which needs attention only to the wrist pin and piston rod fits, the value of having proper guide sizes can be appreciated.

To reduce the number of charts required, driving box information can be secured from a study of the wheel chart. As side and main rods have already been standardized to a considerable extent, blue prints can be used for this item. Thus to protect these five general items of heavy roundhouse repairs, but three charts are needed. The necessary information to give correct measurements has already been secured by the back shop forces and the outside terminal receives incalculable benefit by utilizing information that the back shop usually considers of no value, and for years has thrown away. Thus a calibrating system can be organized and put into use by compiling data that is available at every repair shop.

A BALL BEARING TURNTABLE

BY G. H. BAILEY

A ball-bearing turntable, made of two old locomotive driving wheel tires for a 72-in. wheel center, is shown in the illustration. The advantages of this turntable are simplicity, low cost of construction and durability. When once installed the expense and trouble are over, as the life of a ball bearing, if it is kept well oiled, is practically unlimited.

Two old tires of 72-in. wheel center can be found about the scrap dock of almost any railroad shop and can be utilized to make this turntable without much difficulty. A 3-in. ball would be best for the bearings if the tire is not too thin

The Tires Turned With a Dust Cover

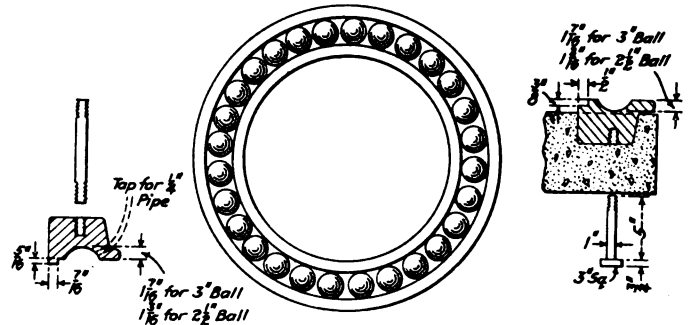

and has at least a 5-in. face to work from, as balls of this diameter are being used by many railroads for swinging rotary cranes and rotary air hoists. A ball as small as $1\frac{1}{2}$ in. may be used if the tire is not thick enough to permit making a race for the 3-in. ball, the size of the ball being dependent on the tire available.

In turning or milling out this ball race a clearance of about $\frac{1}{32}$ in. should be allowed on each side of the ball, so that friction on the balls will not be created when the turntable is in operation. When turning out this race a light cut should also be taken across the face of the tires, so that high spots will not interfere when the tires are placed together. About $\frac{1}{8}$ -in. opening must be allowed between the tires when the balls are in the race and the tires are placed in position, as the balls will wear the tool marks down somewhat, and then the tires will still clear at least $\frac{1}{16}$ in. The tires should come close together, so that the dirt will not collect and get into the race with the balls. An offset on the tires, as shown in the drawing, takes the thrust off the balls when a heavy weight is being placed on the table. This

offset should have $\frac{1}{16}$ -in. clearance, so that the tires will come in contact when a weight is being placed on the table and prevent the crushing of the balls.

A somewhat more expensive, but much more desirable, method of turning-up the tires is also shown in the drawing. In this method the upper tire is machined to overlap and project below the lower tire. This provides a cover to protect the ball bearings from the dirt that collects around the edge of the turntable.

The lower tire is embedded in concrete with six 1-in. by 5-in. bolts having a 3-in. square head and screwed into the under side of the tire to serve as stays to hold the tire firmly. The upper tire is fitted with 1-in. studs of the proper length to suit the turntable that is to be built and as many studs as

Turntable Made from Scrap Tires

may be necessary to hold the table securely to the tire. A $\frac{1}{4}$ -in. pipe should be drilled and tapped into the upper tire, with the pipe running up to the top of the table, so that the bearings can be oiled with fluid oils or with a pressure gun using hard oils or grease. A cap should be provided to fit over the top of this oil pipe to exclude dirt from the bearings. The concrete bed should be arranged to provide for connection to the drainage system.

WELDING LOCOMOTIVE FRAMES

BY M. C. WHELAN

Blacksmith Foreman, St. Louis-San Francisco, Kansas City, Mo.

In thermit welding the practice of heating the lower member when the top is broken is not satisfactory, unless the lower member is kept hot until the top is cold, and in most cases by the time that the black heat contraction is taking place the lower member has been entirely cold for some time. As a result the strain on the weld is tremendous. The method described supersedes the practice of jacking up or distorting the frame to procure expansion and keeps the frame in alignment at all times. The method is not an experiment, but has been adopted and used after a thorough study of the other methods in vogue. The following instructions to be followed in connection with the sketch fully describe the procedure referred to.

When the frame is broken at A, the top and bottom should be trammed at J and J' and expanded by heating the pedestal

jaw at *I*, using bar and wedge *H* or jack, care being taken that the top and bottom tram marks show the same amount of expansion. After the frame at *I* is black hot, the bar *H*, or jack, may be removed, as no pressure remains. After the wax pattern and mold box are applied a fire brick furnace should be constructed so that heat will radiate around the frame jaw at the same point where the heat was applied to expand—namely, *I*. Two hours and a half after the crucible is tapped, and when contraction is started in the weld, *I* should again be heated through a hole in the furnace to a good high heat and then all holes in the furnace should be closed. The frame should then be luted with clay to retain the heat and allowed to contract to the original length while cooling at *A*. The following morning the frame should be heated again at *I* and

Welding Diagram for Locomotive Frame

at *B* to a low red heat. This will eliminate any strain which may remain from uneven cooling of *A* and *I*.

If this procedure is followed there will be no strain tending to break the frame at or near the part repaired. A glance at a broken frame in the box section will often show the enormous strain left in the frame by the fact that it is 1/32 in. to 3/32 in. apart at the break.

When a frame is broken at *B* it should be heated at the same place as if broken at *A*—namely, at *I*. It should be wedged for expansion at *B*, after which the furnace should be placed at *I* and heat applied 2½ hours after the weld is made. Heat should again be applied at *I* and *B* as a final preventive against strain. This method may be applied at any point on the frame. If the break is at *D* the frame should be heated for expansion at 2 and wedged at *H*, using the furnace at 2, and lastly heating at 2 and 4. If at *E*, it should be handled in the same way by heating at 3, using the wedge *H* at *L*, and lastly at 3 and 4.

In welding a heavy frame at *D* and *G* recently a great deal of labor was required to strip for room, so that both frames could be welded at the same time in conformity with our practice. The frame was spread at *M* for the weld at *D*, after which, by heating at 2 and wedging at *G*, the weld was made at *G* by using the furnace at 2 and finally heating at 2 and 4 (3/16 in. expansion is enough for heavy frames when using this method, as there is no pressure against the frame until the jaw is hot, after which the frame contracts naturally and uniformly). This procedure will not distort the jaw.

A number of welds have been made at *F* under the saddle, which is a difficult place and requires at least 4½ hours to heat properly in order to make a successful weld. Care must be taken to have the heating gate so set that the heat will strike directly on the heavier member of the broken parts. If the heavier part is hot the heat from that part will heat the lighter one. Expansion at this point is gained by placing a heavy rail across and through the jaws of both frames and a heavy jack placed between the saddle and this support.

When frames are broken at *C*, expansion is gained in the usual way by the use of bar *H*, as shown in sketch. Welds at *C* and *F* require about 3/32 in. more expansion than with the expansion system of heating, on account of the pressure on the weld when contraction is taking place after the wedge is out.

If the wax pattern and mold boxes are properly applied, the pouring gate made high enough to overcome any back

pressure when the metal rises in the mold and the frame heated up to at least 1,100 deg. F. before tapping, no failures will occur where this method is followed. To obtain the temperature required for large breaks, such as 5 in. by 12 in. or over, two heating gates should be used, one on each side if possible, using a double burner preheater. On extra high welds two pouring gates or one sub-gate to assist in carrying the metal should also be used.

IMPROVED METHOD OF FITTING BRASSES

BY A. W. C.

When a main pin brass is being fitted to the pin it is a general practice to file away the portion of the brass as shown by the dimension *X* in Fig. 1 for the whole width of the brass, so that it will have no bearing on the pin at these points. It is obvious that if the brass is a tight fit in the rod (and it should be) there is a tendency for the ends of each half brass to close on the pin and cause it to warm up, a condition which is probably further aggravated as the brass gets hot. In the marine type or stub end rod (the name generally applied to a main rod of the type that has no strap but an open end), if the block is a trifle smaller than the brass, the closing together of the rod ends when the bolt is tightened will also cause the brass to pinch on the pin, so the advisability of filing this clearance is apparent.

The following method of providing clearance at this part of the brass has given good results: Before the brasses are bored, galvanized iron liners about .025 in. thick, of the shape shown in Fig. 2, are placed between the half brasses, one at the top and one at the bottom. The brasses are bored out .035 in. to .040 in. larger than the pin, and it can be easily seen that when the liners are removed and the half brasses are placed together the bore of the brasses measured horizontally is from 10 to 15 thousandths larger than the pin, which is a good fit for this class of work, and when measured vertically is 35 to 40 thousandths larger than the pin, giving a very reasonable clearance at both top and bottom of brass. This method has the advantage of providing a positive, uniform clearance and eliminates all guesswork upon the part of the

Brass and Liner Used for Obtaining Clearance

Dimension *X* indicates approximate points between which clearance is given.

workman fitting the brasses. After boring, only a small amount of scraping and spotting is necessary to complete a good fitting brass.

It is not unusual for a machinist to allow the calipers a small amount of side-play when boring a hole for a running fit to indicate that the hole is a small amount larger than the size the calipers are actually set for. If only the usual amount of side-play is given in this case, it is obvious that when the liners are removed the brass will be found bored the thickness of the liner too small, as the brasses will not butt together over the pin. If a piece of galvanized iron about 1/16 in. wide, of the same gage as the liners, is used to place one leg of the calipers on, the usual amount of side-play may be given and no difficulty in making a good fit will be experienced.

A Flue Rattler Which Cleans by Friction

A DRY flue cleaner of the revolving drum type which removes the scale by friction between the tubes instead of by impact, has been developed by the Baird Pneumatic Tool Company, Kansas City, Mo. The inside length of the rattler drum is adjustable for different lengths of tubes, so that a uniform allowance for longitudinal movement in the drum may be maintained. The cleaner is loaded through one end of the drum and the entire load of cleaned tubes is ejected in one operation.

The rattler drum has a diameter of 50 in., and is 25 ft. long inside. It has a capacity of 300 two-inch boiler tubes, 250 2¼-in. boiler tubes or 50 superheater flues. From one

car, or cradle, if crane service is available, thus eliminating one handling of the tubes.

The drum is driven by a 25 hp. motor operating at 900 revolutions per minute through gears which reduce the rotation of the drum to 30 revolutions per minute. The cleaning process is simple and effective. Rattlers of the usual type depend on the shock of impact of the tubes against each other to crack and remove the scale. In the Baird rattler the tubes are not subjected to impact, but are rotated one against another. The friction of this rotation generates a large amount of heat, and the rise in temperature causes the cracking and removal of the scale. As the scale is removed

Baird Flue Cleaner

to six hours per load is required for thorough cleaning, the time depending on the nature and thickness of the scale.

One end of the drum is closed with double doors hinged at opposite sides, through which the tubes are placed in the drum. At the opposite end is placed a movable bulkhead, which is operated by the piston in a 14-in. air cylinder. For tubes requiring less than the full length of the drum, this bulkhead is moved in far enough so that the length of the cleaning chamber is but six inches longer than the tubes to be cleaned. The length of the air cylinder is such that, after the tubes have been cleaned, the bulkhead may be used to push the complete set ejected from the drum into a push

in this manner it is pulverized by the movement of the flues against each other, all moisture is expelled by the heat, and the pulverized scale, which ultimately assumes the fineness of flour, forms an effective scouring compound. The finely ground material has a tendency to rise in the revolving drum, from which it finds outlets through slotted openings near the ends of the drum. The portions of the drum containing these openings are enclosed in dust-tight rooms which prevent the scattering of the fine scale through the shop and keep it away from the gears and driving mechanism. Coming from the drum, the tubes are clean inside and out.

The first Baird rattler was installed in the shops of the

Atchison, Topeka & Santa Fe, at Topeka, Kans., over five years ago, and there are now ten installations in service on five railroads. At the time of the first installation, the new machine was confronted with an accumulation of some 200,000 dirty tubes, and for the first nine months after it was placed in service it operated 24 hours a day. Since that time it has been operated 16 hours a day. After a total operation of nearly 40,000 hours, the only cost of maintenance or loss of time was the result of an accident caused by the dropping of a bolt into the gears. The accumulation of tubes was cleaned up and the rattler has since kept up with the shop production. The service of this instal-

lation has also resulted in the elimination of warped and broken tubes, which are regular accompaniments of the use of rattlers of the impact type.

The total length of the Baird machine is 54 ft. 3 in., and its greatest width, at the base plates under the central portion of the drum, is 85 in. The base plate itself is 15 ft. 2 $\frac{3}{4}$ in. in length by 5 ft. 10 in. wide, and the center of the cylinder is 5 ft. 8 in. above the base plate. The overall height is 8 ft. 2 in. As is shown in the illustration, the 14-in. air cylinder for operating the movable bulkhead may be extended outside the building in which the rattler is located, thus materially reducing the amount of floor space required.

Open Side Planer for Railway Shop Use

WHILE open side planers have not been used extensively in railway shops in the past, there is no doubt but that certain planing operations can best be performed on this type of machine. For example, a deck casting 44 in. wide that had been cracked and welded, might require planing on one side. This light job could be done on a 30-in. open side planer, but would require a heavy 48-in. double housing planer to pass the casting between the housings. There is no objection to the open side planer on the ground of its lack of rigidity. Heavy cuts may be taken on an open side planer with the cutting tool and cross rail head seven feet, or even more, from the housing.

Manufactured by the Liberty Machine Tool Company, Hamilton, O., the open side planer illustrated is designed to stand the stresses peculiar to this type of machine. Due to the rigid construction of the bed, column and cross rail, it is possible to take cuts up to the capacity of modern tools. The unit system of parts makes it possible to attach any additional units after the planer is installed, and should it be desired to use the machines as a double housing, four head planer, the left-hand housing and head can be attached at any time. Ample safety appliances protect both the operator and the machine at all times.

The planer bed, extending to the floor, affords a solid foundation for the machine. The top is closed between the tracks, except through the gearing section, which is reinforced by heavy girths. The tracks are wide and V-shaped, with an ample spread to eliminate unnecessary overhang of the table. Lubrication is furnished by automatic rollers. The running gear is placed inside the bed, easily accessible from the top. All torsional strains on the shafts are relieved by pressing the gears on to the pinion hubs.

By careful design, especially of the pulleys, the shifting mechanism shifts the belts quickly and quietly and there is no accumulation of dirt on the cam and other moving parts due to the mechanism being enclosed. By means of shifting

levers on both the front and rear sides of the machine, the operator can control the motion of the table without walking around the planer. A safety lock is provided to prevent accidental starting. The T-slots in the table are planed from the solid stock and reamed holes throughout the entire table length afford ample facilities for clamping. The column

General View of Liberty Open Side Planer

is of the two-faced box type construction, extending to the floor. It is bolted and doweled to the side of the bed and the wide base is arranged for bolting to the foundation.

In operation, the power is transmitted from a spur gear on the end of the bull pinion shaft through a pair of reversing mitre gears to the vertical splined feed shaft. A handle conveniently located determines whether the feed is to take place on the cutting or on the return stroke. With the handle in a neutral position, all feeds are disengaged.

The amount of feed is determined by adjustable stops operated by a knob. Among the advantages of the special patented feed may be mentioned the possibility of controlling or changing the feed or rail head position at any time without stopping the machine or disturbing the feeds on other heads. Feed indicating dials enable the operator to set the feed at any required amount.

Great care was exercised to secure a rigid cross rail. It is triangular in shape, with a long and narrow guide extending upward on the front of the column. It is bolted and doveled to the triangular brace or knee which extends to the rear of the column, where it is rigidly clamped by T-slot bolts in addition to a rail clamp.

Both cross rail heads are provided with long and wide bearing surfaces on the cross rail and are made right and left for close range. They are graduated for swiveling up to 90 degrees, and have automatic feeds in all directions. A great convenience to the operator results from the power elevating device located on top of the column.

The side head is mounted on the front of the column to avoid any unnecessary overhang of the tool which is brought up close to the point of support. The side head is properly counterbalanced, provided with automatic feed, and can be swiveled. The tool block is fitted with a heavy releasing spring plunger. The Liberty open side planers are made in four sizes: 30-in., 36-in., 42-in. and 48-in.

Drill Press Equipped With Electric Control

BOTH a.c. and d.c. electric control have been applied to the heavy duty drill presses shown in the illustrations and manufactured by the Colburn Machine Tool Company, Franklin, Pa. One drill press is equipped with a Cutler Hammer alternating current electric control and the other with a special direct control for reversing the spindle for tapping operations. Colburn drill presses have been arranged for reversing the spindle when provided with direct current motor drive for some time, but it is only recently that any equipment has been available which would reverse the spindle satisfactorily when alternating current motor drive was used.

The alternating current equipment (Fig. 1) consists of an

Fig. 1—Colburn Drill Press With Alternating Current Control

automatic motor starter and a reverse switch. The automatic starter is contained in a metal box which may be mounted directly on the machine or fastened to the wall as illustrated. The reverse switch is mounted on the column of the machine directly above the feed gear box, and is connected to the operating lever by sprockets and chain. It has three positions; forward, neutral and reverse.

The operator when tapping a hole, simply throws the lever to the forward position and when the tap reaches the desired depth, throws it to the extreme opposite (reverse) position which reverses the spindle instantly and withdraws the tap. To stop the machine, the lever is thrown to the neutral position.

For direct current equipment (Fig. 2) there is an automatic motor starter and reverse switch which differs somewhat in mechanical detail from the alternating current equipment. In the illustration the starter and reverse switch are shown mounted directly on the column of the machine. This reverse switch also has three positions; forward, neutral and reverse and the control is carried to the operating lever at the front by means of a lever and link.

In operation the d.c. mechanism acts similar to the a.c. Throwing the lever to the forward position starts the spindle.

Fig. 2—Colburn Drill Press With Direct Current Control

Throwing it to the extreme opposite position reverses the spindle and throwing it to neutral, stops the spindle immediately. The illustrations show reversing a.c. and d.c. motor control as applied to the larger Colburn drill presses but either style of control is readily adaptable to the smaller sizes. The advantages of the electrical control include increased life of the machine due to a reduction in shocks and jars, and a considerable saving in taps that would otherwise be broken.

Recording Instrument for Road Locomotives

THE model K Loco-Recorder is a durable American-made machine, designed to indicate a locomotive's speed at all times to the engineman and give a permanent record of that speed, also the direction of motion, whether forward or back, and the time spent at station and other stops. The instrument increases the safety of train operation by practically eliminating the danger incidental to excessive speed on curves or at other points where there are speed restrictions. By furnishing an accurate record of the speed at all points there is a

applied to the ring shown, which actuates the indicator pointer, showing the exact speed at which it is running.

Two pencils operate independently of each other on the chart, one showing speed and the other time. The recording tape is driven by the locomotive through a connection with one of the driving wheels and moves at the rate of half an

Internal Mechanism of the Speedograph Loco-Recorder

The Recording Mechanism is Protected by the Metallic Cover Which Can Be Securely Locked

tendency to prevent unnecessary wear and tear on motive power, rolling stock and tracks through express train speeds of locomotives built for slow and heavy service. The need for such an instrument is especially urgent at the present time because of the increased costs of labor and material and the much larger and heavier locomotives and cars.

Two views of the instrument illustrates its general appearance and working mechanism, and part of a typical record

inch to the mile in keeping with the speed of the locomotive; when the locomotive stops the tape stops, and when the locomotive reverses the tape also moves backward. This makes the record easily adjustable to a keyboard, representing in

Reproduction of Part of a Record, Covering 19 Miles, Made by a Locomotive in Regular Service

made by a locomotive in regular service also is reproduced. The entire story of train operation is recorded so clearly and concisely on the strip of recording tape that it can be read at a glance. Part of the instrument is built on the plan of a speedometer, depending for its action upon centrifugal force

the same ratio the division over which the train is operated. Stations, towers, sidings and all points at which there are speed restrictions are shown on the keyboard, together with any other desired information. By placing the record against the keyboard the speed at all points and the location and

duration of all stops and slowdowns are clearly shown. The tape is calibrated horizontally in miles per hour to facilitate the reading of the speed record, and perpendicularly in miles of track, with heavy lines every five miles.

The speed pencil moves across the tape in proportion to the speed of the locomotive. It returns to zero at the top of the tape at every stop, and acceleration and deceleration are plainly shown. Its action is positive and every change of speed is instantly indicated on the dial and recorded on the tape. The pencil accurately records the speed shown to the engineer on the dial; the mechanism is so interlocked that it can record nothing else. Changes of gears to compensate for the turning down of tires are furnished with each instrument to insure precise accuracy in speed indications and records.

The time pencil is actuated by a clock and moves back and forth across the tape in 10-minute strokes; 10 minutes up and 10 minutes down. When the train is in motion this pencil makes an angular line, the angle depending on the rate of speed, and when the tape stops it makes a straight vertical line, the length of which shows the duration of the stops, on the basis of $\frac{3}{16}$ in. to a minute. This records the length of all stops up to 20 or 30 minutes in length. The dial pointer, which indicates the speed to the engineer, is the only

working part of the instrument that is exposed to observation. The cover of the case completely encloses the recording mechanism and tape and is securely locked.

The record illustrated was made by a locomotive moving from the right to the left, and *A*, *B*, *C*, *D* and *E* are stops. The line connecting these points is made by the speed pencil, and shows the speed at all points and the distance covered in bringing the train to a stop and picking up speed again.

Referring to the record, *A'*, *B'*, *C'*, *D'* and *E'* are vertical lines made by the time pencil giving the length of stops at *A*, *B*, *C*, *D* and *E*, respectively. They show stops of approximately one minute at *A*, *B* and *C*. After stopping for about two minutes at *D* the train was backed, at a maximum speed of about 13 miles an hour, an eighth of a mile to *E*, where it stopped for nearly three minutes before resuming its run. It attained a speed of 57 miles an hour in three miles after leaving *A* and immediately began to slow down for *B*. The highest speed of this train, on the section of its record shown, was 60 miles an hour before reaching *D*. Midway between *B* and *C* the speed was sharply reduced from 53 to 44 miles an hour, but was immediately increased. From the foregoing it is evident that a complete, detailed record is available of train operation over the division in question.

Red E. High Speed Lathe Center

LATHE and grinding machine centers made of carbon steel often burn at the points and freeze to the work. It has long been recognized that high speed steel centers would obviate such difficulties and allow the machine to be

Lathe Center With High Speed Steel Point

operated at its maximum capacity, but high speed steel is expensive. It would seem poor economy to make a lathe center entirely of high speed steel when possibly less than $\frac{1}{2}$ in. of

the point would be used, the rest going into the scrap bin.

The Ready Tool Company, Bridgeport, Conn., has offered one solution of the problem by making a solid lathe center with a nickel steel body and a high speed steel point. The high speed steel extends back from the point about one-quarter the length of the lathe center. On account of its solid construction, vibration is reduced to a minimum and due to the high speed steel point, the lathe center life is increased many times.

The advantages of the Red E. lathe center include not only the possibility of machine operation at a higher speed but a considerable saving in the machinist's time previously spent in grinding centers. The center is made with Morse and Jarno standard tapers, and will fit any standard make of lathe or grinding machine.

Anti-Slip Surfacing Decreases Accidents

THE hazards due to dangerous walking places are underestimated by many people, who doubtless would be surprised at the large proportion of accidents due to so apparently harmless a thing as slipping. It is difficult to get conclusive data on the subject, since casualties are often charged erroneously to other than promoting causes, yet the

Fig. 1. View Showing the General Appearance of Vulcalum

casualties resulting from unsafe walking are greater in number and severity than those due to any other public or industrial hazard. Based on U. S. mortality statistics, the total fatalities for the continental United States were 76,500 in 1915. Of these fatalities, 14,855 were caused by falls, over half of which occurred on stairs and oor levels.

With the above facts in mind, it is evident that too much

care cannot be taken to provide safe walkways, inclines and steps in all public buildings, passenger cars and coaches. In addition, running boards and surfacing around the switch boards in power houses, where a slip may result fatally, should be surfaced with a material that will prevent slipping.

A new form of abrasive walkway surfacing called Vulcalun, has been placed on the market by the American Abra-

Fig. 2. Cross Section of New Abrasive Metal Surfacing

sive Metals Company, New York, and is proving satisfactory under exhaustive tests. Vulcalun is a mixture of rubber and abrasive grit vulcanized to a steel reinforcing plate contained entirely within a pure rubber base. A good idea of the general appearance of the substance is given in Fig. 1, which shows a sample piece. A cross section of the sample is shown in Fig. 2, in which *A* is the abrasive grit, *B* the perforated steel reinforcing plate and *C* the rubber base.

One result of the tests referred to was definite proof of the value of Vulcalun in the prevention of slipping. On a new

railway station stairway equipped with corrugated treads and subject to heavy passenger traffic, there was an average of two falls a day for a period of two months. With abrasive metal treads substituted, the succeeding two months failed to show a single fall.

Owing to the abrasive rubber surface and steel plate Vulcalun resists wear and will not crack under severe vibration. The material is adapted not only to walkways and coach steps, but due to a high dielectric strength, is desirable for surfacing around switchboards in power houses. Tests have

shown that there was no electric leakage through the material up to 7,500 volts and the flashover did not occur under 20,000 volts.

Vulcalun is light in weight, above $3\frac{1}{2}$ lb. per sq. ft., and therefore is desirable for elevator car floors in freight houses and shops. Due to being enveloped entirely in a rubber base the steel reinforcing plate does not corrode; there is no tendency to disintegrate when saturated and exposed to freezing. The material is uniform in finish and manufacture, easily kept clean, and easy to renew when necessary.

Universal Vice for Pneumatic Drills

THE purpose of the repair vise illustrated is to firmly clamp and hold a pneumatic drill in various accessible positions while making necessary repairs, assembling or testing. The vise should be placed near the repairman's regular bench vise preferably on the right hand side. This arrangement leaves the regular bench vise free to be used should occasion arise. In general the drill may be clamped in any of three positions which may be most convenient for removing the gear case, spindle and valve gear; removing the valves, exhaust caps and feed screw; or for reaming piston holes or general inspection.

As shown in the illustration, the repair vise consists of a flanged upright machine post or stand 1101, a sliding stop collar 1102 held by a suitable set screw 1103, and a clamp 1104 which is securely held in any position on the post by tightening the quick action clamp screw 1105. At the other end of the clamp there is a hole in which stem 1108 is engaged. This stem is threaded at one end with $\frac{1}{2}$ -in. and $\frac{3}{4}$ -in. pipe threads respectively. For the small sized drill, a clamp with a $\frac{1}{8}$ -in. pipe thread is used in connection with a special clamp support.

Pneumatic drills are used very extensively in railway shops and the question of keeping them in repair is always a pressing one. The universal repair vise illustrated will facilitate

in making quick repairs and for this reason is of interest to railway men. The vise is made by the Independent Pneumatic Tool Company, Chicago, Ill.

Thor Assembling and Repair Vise for Holding Pneumatic Drills

Car Hauling Winch Reduces Switcher Work

A NEW type of electric car hauling winch recently developed by the Shepard Electric Crane & Hoist Company, Montour, N. Y., is shown in Fig. 1. The operating units of this machine embody many of the distinctive features of the Shepard electric hoist. All moving parts are

advanced drive type, driving at two diametrically opposite points. This insures long life, high efficiency and a practically noiseless drive.

The winch is mounted on a cast base which encloses the controller resistance. A standard Shepard controller is used

Fig. 1. Shepard Electric Car Hauling Winch

Fig. 2. Car Hauling Winch Installed at Coaling Station

fully enclosed, making the machine entirely weatherproof with the exception of the motor. Oil bath lubrication is provided for all the gearing, brakes, etc. The gearing is of the bal-

which may be mounted directly on the base or separately for remote control. When desired, the machine can be furnished with a gear shift, giving a reduction of four to one. This

enables the winch to handle four times its normal, rated load.

A recent installation of this winch in the new coaling station of the New York Central at Rensselaer is shown in Fig. 2. It is used in place of locomotives to draw loaded coal cars up to the coal dump. The winch capacity is $4\frac{1}{2}$ tons at a speed of 55 ft. per min. and the winding drum has a capacity of 250 ft. of cable. Alternating current is furnished through

a 22-hp., three-phase General Electric motor. Two hundred feet of $\frac{7}{8}$ -in. wire rope are used. The machine is installed in a winch house as shown with the drum extending outside.

In a test made of the Shepard car hauling winch recently, 14 coal cars were pulled around a curve and up a grade after being partly frozen in. The winch is reported to have withstood all tests of winter weather with gratifying results.

Slotting Machine for Tool Room Work

THE slotting machine illustrated has a $6\frac{1}{2}$ -in. stroke and on account of its general adaptability and the arrangement for swiveling the ram, the machine is well adapted for a large variety of tool room work. Taper keyways and other taper work, such as often occurs in machining dies and heavy tools can be performed without difficulty. Many machine operations on special jigs and fixtures can also be performed on this type of slotter.

The machine is cone-driven and of sufficiently rigid construction for any work within its capacity. With a proportionately heavy base and column, ample strength is insured and vibration is reduced to a minimum. Automatic feeds are provided to move both the longitudinal and transverse slides and the circular table. The table, of relatively large diameter, is graduated in degrees and has a locking device with 12 divisions. Swiveling the ram greatly increases the usefulness of the machine for all kinds of taper work and the swiveling arrangement is simple as shown in the illustration.

A universal tool holder of the clapper type is provided. All gears are mounted rigidly and the bearings are dustproof and oiltight. The countershaft is self-contained and the treadle brake shown projecting beneath the table enables the operator to stop the machine with the ram in any desired position.

The stroke of the ram is $6\frac{1}{2}$ in. and work $7\frac{1}{2}$ in. high can be placed on the table. The maximum diameter of work that can be machined is 30 in. but the effective diameter of the rotary table is 16 in. The longitudinal and transverse

travels are 12 in. each, and the speed ranges from 26 to 77 strokes per minute. The machine is manufactured by Harry F. Atkins, Peterborough, England, and is being placed on the American market by Alfred Herbert, Ltd., New York.

Atkins Slotting Machine With $6\frac{1}{2}$ In Stroke

Fullswing Relieving Attachment for Lathes

SEVERAL new features have been included in the heavy duty relieving attachment illustrated, by means of which it is possible to perform a class of work not usually attempted on this type of lathe attachment. Interior relieving

work may be mentioned as an example and in addition, all kinds of outside relieving work, including any angle, side, face, interior or irregular face flutings and taper cutting can be performed. Designed to stand hard machine shop usage,

Relieving Attachment Designed for Accuracy Under Heavy Cuts

the Fullswing relieving attachment is made in three horizontal sections, two of which remain stationary after alinement. They can be applied to any lathe equipped with a compound rest. The sections are graduated for angles of any degree and the tool holders can be moved for any axis of motion without reference to the tool. The relieving head is mounted on the single base in place of the compound rest and is driven from the nose of the headstock by a mounted gear through a train of gears as indicated. A universal joint between the spliced shaft and the relieving head allows for movement of the cross slide.

The entire mechanism is direct geared or stationary, with the exception of the reciprocating tool holder which operates in a V-guide, provided with a bronze gib. This direct connection saves lost motion and increases the accuracy and sensitiveness. A hand cross feed of three inches is provided

on the tool holder for cross relieving, either straight or at an angle, thus permitting a class of work not usually attempted. Another distinctive feature is the provision in the tool holder for the vertical adjustment of the tool bit with a range of $\frac{3}{8}$ in.

The attachment will operate in connection with the taper attachment of the lathe for relieving conical cutters and pipe reamers. Form contour cutters can be relieved when desired. A standard relief of $\frac{1}{10}$ in. is provided, but special cams can be furnished for a greater or lesser relief. A set of four cams with one, two, three and four steps is furnished with each attachment for the operation of various flutings. A set of special gears can be furnished to relieve special formed cutters. In tool rooms and machine shops that manufacture milling and other cutters, the Fullswing relieving attachment can be used to good advantage.

Modern Refinements in Shaper Design

THERE has been a continual refinement in machine tool design in recent years to make the machines not only more efficient but adaptable to a greater variety of machine operations. The shaping machine has been no exception to this rule, and many improvements are included in the 24-in. heavy duty crank shaper manufactured by the Columbia Machine Tool Company, Hamilton, Ohio. Among these improvements may be mentioned the adaptability to either single pulley or motor drive. Additional features include a speed box, friction clutch and brake and revolving table having an outer support to provide additional stiffness.

The speed box provides four changes of speed, or eight changes in connection with the back gears. The friction clutch and brake enables the machine to be started or stopped quickly at any point of the stroke. By special design the feed box is included as part of the machine and not as an attachment, and the arrangement provides a rigid and efficient feed device. Twelve feed changes are provided, ranging from

the speed box is simply extended through an additional bracket on the other side of the shaper. This allows the single pulley to be mounted on the outside and driven from the line shaft. The advantage of a friction brake in stop-

Columbia 24-in. Shaper With Modern Improvements

$\frac{1}{54}$ in. to $\frac{3}{16}$ in. The feed takes place only on the return stroke and the mechanism automatically adjusts itself to the position of the cross rail.

Arrangements for either motor drive or single pulley drive can be made with slight alterations. In case a motor drive is desired, the power from a direct current motor is transmitted to the speed box through a rawhide gear, as illustrated. With the single-pulley drive arrangement, the main shaft of

View Showing Adaptability to Motor Drive

ping the shaper in any desired position of the ram is self-evident.

Important advantages in the crank gear construction are its liberal proportions and the fact that it is carried close to the rocker arm, thus reducing torsional strain to a minimum. The rocker arm also is of heavy construction, the sides being joined by a strong central tie. It is connected to the ram through a heavy link, which affords a direct pull on the ram.

The revolving table is plainly illustrated, and a noteworthy feature is the construction of the outer support which stiffens the table and maintains the alinement of the faces. In addition to the outer support, the table is carried on a hub, or trunnion, of large diameter, which is bolted securely to the saddle. The table rotates on this trunnion and is graduated at the outer end so that it can be set at any desired angle. A rugged double screw vise with graduated swivel base is regularly furnished with the machine, but a single screw vise can be furnished if desired. The vise jaws are steel faced and suitable clamp screws prevent the movable jaw from lifting. On the double screw vise the jaws are offset to facilitate holding work alongside the table, if required.

Subscriptions, including the eight daily editions of the Railway Age, published in June, in connection with the annual convention of the American Railroad Association. Section III—Mechanical, payable in advance and postage free: United States, east of the Mississippi river, \$3.00 a year; elsewhere, \$4.00 a year; Single copy, 30 cents.

WE GUARANTEE, that of this issue, 12,350 copies were printed; that of these 12,350 copies, 11,423 were mailed to regular paid subscribers, 10 were provided for counter and news company sales, 229 were mailed to advertisers, 32 were mailed to employees and correspondents, and 656 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 61,150, an average of 12,230 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

The Texas & Pacific machine shop at Big Springs, Tex., is reported to have been destroyed by fire on March 29. Steps will be taken at once to rebuild the shops on a larger scale.

The Canadian Pacific has offered, subject to competitive examination, a free scholarship covering four years' tuition in either architecture, chemistry, civil, mechanical or electrical engineering at McGill University, Montreal, to apprentices and other employees enrolled on the company's permanent staff under 21 years of age and to sons of employees under 21 years of age.

It is reported that plans for largely increasing the number of workmen employed at the Americus, Ga., shops of the Seaboard Air Line are under consideration by officers of the company. The only other shops of the system are located in large cities and the belief that labor difficulties are less likely to occur in small industrial centers is said to be the reason for rehabilitating the Americus shops.

D. B. Hanna, president of the Canadian National, is preparing to lay before the Canadian Parliament an extensive program for increased efficiency and betterment of equipment of the Canadian National. Complete details will not be made public until the matter is laid before the Parliament at the coming session. Beyond stating that there would be no curtailment of last year's appropriations, Mr. Hanna has declined to make any further statement.

The following railroads have ordered a total of 87 of the total of 200 Decapod locomotives originally built for the Russian government, which the War Department has been trying to sell: Western Maryland, 10; Detroit, Toledo & Ironton, 15; St. Louis-San Francisco, 10; Atlantic Coast Line, 10; Charleston & Western Carolina, 3; Norfolk Southern, 4; John Ringling, 5; Seaboard Air Line, 20; St. Louis, Brownsville & Mexico, 5, and Nashville, Chattanooga & St. Louis, 5.

Domestic orders for locomotives up to the third week in March totaled 635, as compared with 1,048 in 1917, 926 in 1916, and 174 in 1915. This means, of course, that the volume of business this year, from the standpoint of number of locomotives ordered, has not been as great as in 1917 or 1916. It can also be taken to mean, in view of the underlying conditions, that the difference in volume as between this

year and the two years, 1916 and 1917, has still to be made up and may eventually be added to the totals for the present year.

American Machine Tools in the Dutch East Indies

American machine tools are rapidly gaining an enviable reputation in this market, writes Consul Harry Campbell, Soerabaya, Java. One of the largest and most successful machine shops in Soerabaya is completely equipped with modern American machine tools and is securing an abundance of orders for shopwork which, it appears, it is able to fill more satisfactorily than any of its competitors. It is announced that this concern has recently been awarded the contract for the iron and steel work of a new government railway terminal at Tandjong Priok, the port of Batavia. This speaks well for the Soerabaya shop, with its American equipment, in view of the competition of Batavia firms located so much nearer the work.

Plans for Use of \$300,000,000 Loan Fund

Plans for the use of the \$300,000,000 revolving fund, placed at the disposition of the Interstate Commerce Commission to make loans to railroads, were discussed at a conference on March 25 by a committee representing the Association of Railway Executives with Commissioners Clark, Meyer, Daniels and Eastman, Director General Hines and R. B. Leffingwell, assistant secretary of the treasury.

Among the questions discussed was as to whether most of the available sum would be used to greatest advantage if invested in terminal improvements, etc., or in equipment.

It is understood that the executives, represented by T. De Witt Cuyler, Samuel Rea, Howard Elliott, Daniel Willard, Henry Walters and Alfred P. Thom, were inclined to urge the use of the fund largely for equipment, both because of the great need for it and because equipment can be purchased for a 25 per cent initial payment, and the fund would, therefore, accomplish more than if used otherwise.

The purchase of 80,000 freight cars, 20,000 refrigerator cars, 2,000 passenger cars, and 2,000 locomotives was discussed.

The railroads' program of capital expenditures also de-

depends on how soon they can collect from the Railroad Administration for rental due. Director General Hines is expected to ask Congress soon for an appropriation of over \$400,000,000, which will enable him to make further payments to the roads.

Catalogues for Mesopotamian Railways

The Department of Overseas Trade, 35 Old Queen street, S. W. 1, advises that it has received information to the effect that the superintendent of stores of the Mesopotamian railways, in order to facilitate the preparation of demands and also for his general guidance, is desirous of obtaining copies of manufacturers' catalogues dealing with all kinds of railroad equipment and machinery, including locomotives and rolling stock, standard, meter gage and narrow gage; steam and oil pumps of all descriptions; motor rail cars, machinery—workshop, repair and manufactory; heavy and light tools as used on railways; lights, piping and fittings; general hardware; cranes; general electrical plant and accessories; engines—stationary and portable, steam and oil; conveyors, elevators, etc.; labor-saving devices generally. The catalogues should be forwarded directly to the superintendent of stores, Mesopotamian Railways, Makinah, Mesopotamia.

Italy Looking to Germany for Locomotives

Italy, which during the past two or three years has placed large orders for locomotives in the United States, is now looking to Germany as a source of supply. The reason for this, as explained in Commerce Reports in a communication from Alfred P. Dennis, commercial attaché at Rome, is the low purchasing power of the Italian lira in the American market. "It is a question," says Mr. Dennis, "how soon Germany will be able to satisfy any foreign demands of this sort, however. At the conclusion of the war that country possessed between 12,000 and 13,000 locomotives, 4,000 of which the allies took under the terms of the peace settlement; so that today Germany stands in more acute need of locomotives than does Italy. The situation in Italy is such that for the time it must continue to purchase from foreign sources, and until Germany is prepared to supply the demand the United States must be relied upon, in spite of unfavorable exchange, for whatever locomotives are imperatively needed."

Use of Air Brakes on Swedish Railways

Some few months ago, writes Consul General D. I. Murphy, Stockholm, the Swedish State Railways began to equip their rolling stock with Kunze-Knorr air brakes, a German invention. By the end of this year it is expected that 60 locomotives and 1,000 cars will be equipped with them. A project is before the Riksdag to grant an increased appropriation so that all the rolling stock of the State Railways, consisting of 1,100 locomotives, 2,500 passenger cars, and about 27,000 freight cars, may be provided with this particular brake.

The Swedish newspapers express gratification that the Kunze-Knorr brakes are to be manufactured by Aktiebolaget Nordiska Armaturfabrikerna, at Lund, that company having purchased the manufacturing rights for Sweden, Norway, and Denmark. The private railways in Sweden have been undecided as to the adoption of the air brake system, but the papers announce that there is no longer any doubt as to its adoption.

Division of Purchases Discontinued

The Division of Purchases of the United States Railroad Administration was discontinued on April 1. Henry B. Spencer, director of the division, who has been elected president of the Fruit Growers' Express Company, will become an advisory member of the director general's staff with re-

spect to matters growing out of purchases during the period of federal control of railroads. Such portions of the work of the Division of Purchases as remained to be completed after April 1, with the exception of the completion of activities incident to control over the distribution of coal, are under the direction of the Division of Liquidation of Claims; Max Thelen, director.

Control over the distribution of coal, growing out of the strike of bituminous coal miners, was ended on April 1, in accordance with an executive order of the President. Work remaining to be done in connection with the winding-up of the matters relating thereto is being dealt with in the director general's office, through Brice Claggett, assistant to the director general.

Italy to Use Liquid Fuel for Railway Locomotives

An article in the London Times Trade Supplement says that in consequence of the scarcity and high cost of coal, the Italian Minister of Railways has ordered the immediate remodeling of 100 locomotives for use with liquid fuel. If the results are satisfactory, a further 200 locomotives will be adapted.

In Verona and Florence trials are being made with oil and coal mixed, and in Naples with oil only. Fourteen locomotives have been remodeled and are in use between Brindisi and Bari. All tests made hitherto have been very satisfactory.

The use of liquid fuel on a large scale is the only means of replacing coal quickly, as the electrification of railways can only be carried out in the course of some years. The Italian experiment must be regarded as an attempt to cope with one of the most important economic problems of the immediate future.

MEETINGS AND CONVENTIONS

Pacific Railway Club.—At its annual meeting held in San Francisco, Cal., on March 16, the Pacific Railway Club elected the following officers for the ensuing year: President, Dennistoun Wood, assistant mechanical engineer and engineer of tests, Southern Pacific; first vice-president, G. H. Harris, general superintendent, San Francisco—Oakland Terminal; second vice-president, F. S. Foote, Jr., professor of railroad engineering, University of California; treasurer, G. H. Baker, assistant general freight agent, Atchison, Topeka & Santa Fe; secretary, William S. Wollner, general safety and welfare agent, Northwestern Pacific.

National Machine Tool Builders' Association.—The annual convention of this association, of which Albert E. Newton, vice-president and general manager of the Reed-Prentice Company, Worcester, Mass., is the president, will be held at Atlantic City on May 20 and 21. At the same time the American Supply & Machinery Dealers' Association, the Southern Supply and Machinery Dealers' Association and the National Supply and Machinery Dealers' Association will also meet at Atlantic City. Many machinery manufacturers and dealers from all over the country will be represented.

American Foundrymen's Association.—A new department to be known as the Non-Ferrous Casting Section, will be added to the program of the next annual meeting of the American Foundrymen's Association, which will be held in Columbus, Ohio, on October 4 to 8, inclusive. At the meetings of this section papers and discussions of interest to practical brass and aluminum foundrymen will be presented. It is proposed to hold joint sessions also with the Institute of Metals Division of the American Institute of Mining & Metallurgical Engineers, which will hold its convention in Columbus during the same week. The other sections that will

be represented on the program of the American Foundrymen's Association are the Gray Iron, Steel Foundry, Malleable Iron and Industrial Relation Sections, and in conjunction with these meetings will be held the usual exhibit of foundry and machine shop tools, equipment and supplies.

Exhibit at Atlantic City

The exhibit at Atlantic City during the conventions of Section III—Mechanical, and Section VI—Purchases and Stores, American Railroad Association, will be a record-breaker in all respects. Arrangements are being made to place exhibits in the balcony of the main building, thus increasing the total square feet of exhibit space from 93,499 in 1919 to 99,817 ft. this year. Space has been allotted to 335 exhibitors as compared to 301 last year. There are applications for at least 30,000 sq. ft. of space in excess of the total amount available; the Exhibit Committee found it necessary in many instances to cut down the amount of space allotted to some of the applicants in order to take care of a large number of exhibitors. The only way in which additional exhibitors can be taken care of will be by making some arrangement to double up with exhibitors who have already been allotted space.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs:

- AIR-BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 165 Broadway, New York City. Convention May 4-7. Hotel Sherman, Chicago.
- AMERICAN RAILROAD ASSOCIATION, SECTION III.—MECHANICAL.—V. R. Hawthorne, 431 South Dearborn St., Chicago. Convention, June 9-16, 1920, Atlantic City, N. J.
- AMERICAN RAILROAD ASSOCIATION, SECTION VI.—PURCHASES AND STORES.—J. P. Murphy, N. Y. C., Collinwood, Ohio. Convention June 14-16, 1920, Atlantic City, N. J.
- AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—O. E. Schlink, 485 W. Fifth St., Peru, Ind. Convention June 1-4, 1920, Hotel Sherman, Chicago.
- AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—R. D. Fletcher, Belt Railway, Chicago.
- AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 21, 1920, New Monterey Hotel, Asbury Park, N. J.
- AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
- AMERICAN STEEL TREATERS' SOCIETY.—W. H. Eisenman, 154 E. Erie St., Chicago.
- ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.
- CANADIAN RAILWAY CLUB.—W. A. Booth, 131 Charron St., Montreal, Que. Meetings second Tuesday in month, except June, July and August.
- CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 626 North Pine Ave., Chicago. Meetings second Monday in month, except June, July and August. Hotel Morrison, Chicago.
- CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—Thomas B. Koeneke, secretary Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
- CENTRAL RAILWAY CLUB.—H. D. Vought, 95 Liberty St., New York. Meetings second Friday in January, March, May and September and second Thursday in November, Hotel Statter, Buffalo, N. Y.
- CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—J. C. Keene, Decatur, Ill.
- CINCINNATI RAILWAY CLUB.—H. Boutet, 101 Carew Building, Cincinnati, Ohio. Meetings second Tuesday in February, May, September and November.
- INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, C. H. & D., Lima, Ohio.
- INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. G. Crawford, 542 W. Jackson Blvd., Chicago. Convention, May 24-27, 1920, Hotel Sherman, Chicago, Ill.
- INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention Sept. 7-10, 1920, Hotel Sherman, Chicago.
- MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York. Convention May 25-28, Curtis Hotel, Minneapolis, Minn.
- MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION OF U. S. AND CANADA.—A. P. Dane, B. & M., Reading, Mass.
- NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Meetings second Tuesday in month, except June, July, August and September.
- NEW YORK RAILROAD CLUB.—H. D. Vought, 95 Liberty St., New York. Meetings third Friday in month, except June, July and August, 29 W. 39th St., New York.
- NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgrebe, 623 Brisbane Building, Buffalo, N. Y. Meetings, third Wednesday in month, Statter Hotel, Buffalo, N. Y.
- PACIFIC RAILWAY CLUB.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Meetings, second Thursday in month, alternately in San Francisco and Oakland.
- RAILWAY CLUB OF PITTSBURGH.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings, fourth Friday in month, except June, July and August, American Club House, Pittsburgh.
- ST. LOUIS RAILWAY CLUB.—J. B. Frauenthal, Union Station, St. Louis, Mo. Meetings, second Friday in month, except June, July and August.
- TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.
- WESTERN RAILWAY CLUB.—J. M. Byrne, 916 West 78th St., Chicago. Meetings, third Monday in month, except June, July and August.

PERSONAL MENTION

GENERAL

W. A. COTTON, formerly assistant to the general mechanical superintendent of the Erie, at Meadville, Pa., has been appointed mechanical accountant, with the same headquarters.

G. S. EDMONDS, shop superintendent of the Delaware & Hudson at Colonie, N. Y., has been appointed acting superintendent of motive power, succeeding J. H. Manning, deceased.

J. E. ENNIS, corporate assistant engineer of rolling stock of the New York Central Lines, with headquarters at New York, has been appointed engineer of equipment claims, the former corporate title of engineer of rolling stock having been abolished.

ALFRED E. CALKINS, who has been appointed superintendent rolling stock of the New York Central, lines east of Buffalo, with headquarters at New York, as noted in the April

issue, served as engineer rolling stock of the New York Central and the Rutland during the greater part of federal control. Mr. Calkins began railroad work on January 7, 1892, as stenographer in the transportation department of the New York Central. On March 5 of the same year he was transferred to the general office of the mechanical department. He became chief clerk in the car shop at Rochester, N. Y., on February 15, 1898. On September 1, 1899, he

A. E. Calkins

was again transferred to the general office of the mechanical department as assistant chief clerk of the car department and in 1903 he was promoted to chief clerk. Afterwards he was appointed assistant to the superintendent of rolling stock and on August 1, 1918, he became engineer of rolling stock, which position he retained until his recent appointment.

C. A. GILL, superintendent maintenance of equipment of the Baltimore & Ohio, at Baltimore, Md., has been appointed superintendent motive power of the Eastern lines, with the same headquarters.

T. F. HOWLEY, superintendent locomotive operation of the Erie, with headquarters at Meadville, Pa., has been appointed special agent, with the same headquarters.

D. L. MILLS, roundhouse foreman of the Chicago & North Western, has been appointed chief draftsman of the motive power and car departments, succeeding L. P. Michael.

B. B. MILNER, engineer of motive power of the New York Central, with office at New York, has been appointed engineer of motive power and rolling stock, and will be responsible for the design and construction of new equipment (other than electric), standards for repairs, testing equipment, supplies and materials.

JOHN L. MOHUN, assistant to E. E. Adams while consulting engineer of the Union Pacific at New York, has been

appointed mechanical assistant, with headquarters at Omaha, Neb. Mr. Mohun began railroad work as an apprentice in the Altoona shops of the Pennsylvania. Afterwards he became assistant master mechanic of the Juniata shops. He was then appointed assistant engineer of motive power and master mechanic of the New Jersey division with headquarters at Jersey City, N. J. He became assistant to the consulting engineer of the Union Pacific, with headquarters in New York in 1914.

CHARLES I. HYLAND has been appointed mechanical superintendent of the Toledo Terminal with headquarters at Toledo, Ohio. He served as chief boiler inspector of the Michigan Central from January 15, 1919, until the termination of federal control. Mr. Hyland was born on November 3, 1874, at Detroit, Mich. He was graduated from the high school at Jackson, Mich., and began railroad work as an apprentice for the Michigan Central in August, 1891. He was promoted to foreman of the boiler department in July, 1906, and left railroad service in November, 1913, to become boiler expert for the Flannery Bolt Company. He returned to the Michigan Central in 1919 as chief boiler inspector with headquarters at Detroit, Mich.

C. I. Hyland

W. K. LYNN, master mechanic of the Gulf Ship Island at Gulfport, Miss., has been appointed superintendent, with headquarters at Hattiesburg, Miss., succeeding M. D. Fohey.

L. P. MICHAEL, whose appointment as mechanical engineer of the Chicago & North Western, with headquarters at Chicago, was announced in the April *Railway Mechanical Engineer*, was graduated from Purdue University as a bachelor of science in mechanical engineering, specializing in railroad work, in 1896. He was first employed for about one year as a locomotive fireman by the Wabash and Monon Railways, later working as a special machinist helper in the shops of the Monon at Lafayette, Ind. He was then for eight years in the service of the Cleveland, Cincinnati, Chicago & St. Louis and during that time held the positions of machinist, air brake foreman, erecting foreman, enginehouse and general foreman, draftsman and inspector of shops and machinery. Since 1906 he has been with the Chicago & North Western, being employed as a draftsman until 1908, when he was promoted to the position of chief draftsman of the motive power and car departments and held this position until he was recently appointed mechanical engineer.

L. P. Michael

GEORGE C. JONES, whose appointment as general road foreman of engines of the Atlantic Coast Line, with headquarters at Florence, S. C., was announced in the April *Railway Mechanical Engineer*, was born on August 2, 1874 at Fayetteville, N. C., and was educated at Donaldson Academy, Fayetteville. He began railroad work in the shops of the Cape Fear & Yadkin Valley Railway and later acted as a fireman and engineer on that road until it was purchased by the Atlantic Coast Line. He continued as an engineer with that road until December 20, 1909, when he was promoted to the position of road foreman of engines and on March 1, 1920, to his present one as general road foreman.

G. C. Jones

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

F. P. BARNES has been appointed master mechanic of the Colorado, Wyoming & Eastern, succeeding A. D. Howard, resigned.

J. L. BUTLER, master mechanic of the Missouri Pacific at DeSoto, Mo., has been transferred to the position of master mechanic of the St. Louis (Mo.) terminals of the Missouri Pacific.

JOHN J. MULRENEY, general foreman of the North division of the Detroit & Mackinac, has been appointed master mechanic, with headquarters at East Tawas, Mich., succeeding H. T. Thomas. Mr. Mulreney was born on August 15, 1861, at Houghton, Mich., and received his education in the public schools of Jackson. Since June, 1879, he has been engaged in railroad work, having first been employed for three years in the shops of the Michigan Central at Jackson. He then went to Bay City and remained in the employ of that road until September 10, 1889, since which time he has been with the Detroit & Mackinac. In April, 1895, he was appointed general foreman of the North Division at Alpena, Mich., and acted in that capacity continuously from that time until he received his recent appointment.

J. J. Mulreney

F. G. FISHER has been appointed assistant master mechanic of the St. Louis-San Francisco at Monett, Mo., succeeding W. J. Foley, transferred.

W. J. FOLEY, assistant master mechanic of the Northern division of the St. Louis-San Francisco at Menet, Mo., has been appointed master mechanic at Enid, Okla., succeeding A. J. Devlin.

G. B. JEFFERIS has been appointed road foreman of engines of the Stockton division of the Southern Pacific, with headquarters at Tracy, Cal., succeeding W. R. Parker, transferred.

G. H. LANGTON, shop superintendent of the Virginian at Princeton, W. Va., has been appointed master mechanic, with the same headquarters, and the title of shop superintendent has been abolished.

W. R. PARKER, road foreman of engines of the Southern Pacific at Stockton, Cal., has been transferred to West Oakland, Cal., succeeding E. E. House, retired because of ill health.

W. C. ROSS, master car builder of the Copper Range, has been appointed master mechanic at Houghton, Mich., succeeding N. M. Barker, resigned to engage in other business.

CAR DEPARTMENT

JAMES REED, who has been appointed master car builder of the New York Central, fourth district (west), with headquarters at Englewood, Ill., as noted in the April issue, served from 1913 until the termination of federal control as assistant master car builder of the same road, with headquarters at Chicago. Mr. Reed was born in 1869 at Utica, N. Y. He received a public school education and began railroad work in 1888 as car repairer on the Rome, Watertown & Ogdensburg, now part of the New York Central, at Utica. In 1891 he entered the employ of the New York Central as inspector at Herkimer, N. Y., and in 1892 he was transferred to Malone, N. Y., as foreman inspector. While serving in that capacity he was stationed at Lyons, N. Y., from 1896 until 1897, and at Rochester from 1897 until 1902, when he became chief joint inspector at Buffalo.

SHOP AND ENGINEHOUSE

CHARLES P. BOND, whose appointment as foreman of the centralization plant of the Erie at Meadville, Pa., was announced in the March *Railway Mechanical Engineer*, received his education in the Carnegie Technical School, Pittsburgh, Pa. His entire railroad work has been with the Erie, he having entered the employ of that road about 17 years ago as a machinist apprentice. Two years ago he was promoted to the position of shop demonstrator, which he held at the time of his recent appointment.

A. J. DEVLIN, master mechanic of the Western division of the St. Louis-San Francisco at Enid, Okla., has been appointed shop superintendent of the North shops at Springfield, Mo., succeeding J. E. Henshaw, transferred.

F. H. JENKINS has been appointed locomotive foreman of the Canadian Pacific, with headquarters at Brownville Junction, Me.

E. P. POOLE has been appointed supervisor of shops of the Baltimore & Ohio, with headquarters at Baltimore, Md.

PURCHASING AND STOREKEEPING

L. V. GULD has been appointed purchasing agent of the Union Pacific, succeeding G. H. Robinson, transferred.

ALONZO ROSS has been appointed superintendent of stores of the New York region of the Erie, with headquarters at Jersey City, N. J.

OBITUARY

HENRY B. BROWN, superintendent of the fuel department of the Lehigh Valley, died suddenly at his home at Bethlehem, Pa., on April 1, aged 62 years. Mr. Brown was formerly general fuel inspector of the Illinois Central.

HARRY OSBORNE, formerly works manager at the Angus shops of the Canadian Pacific, died at Montreal on March 17, 1920, aged 61.

SUPPLY TRADE NOTES

A new office has been opened by Alfred Herbert, Ltd., New York, at 31 Yonge street, Toronto, Canada, in charge of J. C. Blair.

J. F. Griffin has been appointed chief draftsman of the Locomotive Feed Water Heater Company, 30 Church street, New York.

The Chambers Valve Company, New York, has removed its office from 30 Church street to room 1017, 23 West Forty-third street.

The Bradford Draft Gear Company has removed its New York office from 30 Church street, to suite 1018, 23 West Forty-third street.

Charles C. Kilander, Chicago manager of the American Steam Gauge & Valve Manufacturing Company, Boston, Mass., died on March 18.

The Pennsylvania Tank Car Company and the Pennsylvania Tank Line have removed their New York office from 50 Church street to 25 West Forty-third street.

The Cincinnati Grinder Company is planning a two-story addition in the rear of its plant, 3233 Colerain avenue, Cincinnati, the dimensions being 107 ft. by 60 ft.

Charles A. Beider, assistant manager of sales of the National Malleable Castings Company, Cleveland, Ohio, died in that city on March 13, at the age of 35 years.

M. C. M. Hatch, formerly with the Pulverized Fuel Equipment Corporation, New York, has become associated with the Railway & Industrial Engineers, Inc., 25 Broad street, New York.

John Jeppson, one of the founders of the Norton Company, Worcester, Mass., and for many years a director and superintendent of the plant, died suddenly in Havana, Cuba, on March 26.

A. A. Roelofs, formerly special representative in the Ohio territory, of the Precision & Thread Grinder Manufacturing Company, Philadelphia, Pa., has been made manager of the Chicago office of the company.

Fred J. Passino, who for many years has represented the Independent Pneumatic Tool Company in the Southwest, has been appointed assistant manager of the Eastern division, with headquarters in New York.

Stewart H. Ford recently opened an office at 608 Mutual building, Richmond, Va., and is engaged in the railway supply business, specializing on the Rees car and journal jacks and Hisey-Wolf electric portable tools.

The Mahr Manufacturing Company, Minneapolis, Minn., is now represented in western Pennsylvania by J. L. Edwards, with an office at 498 Union Arcade building, Pittsburgh, Pa. Mr. Edwards succeeded J. S. Longnecker.

J. F. Kroske, who served as a lieutenant with the Nineteenth Engineers during the war, has taken a position in the service department of the Ingersoll-Rand Company, New York, and is connected with its Pittsburgh office.

The Morris Machine Tool Company, Cincinnati, Ohio, has bought the business of the American Metal Products Company, also of Cincinnati, manufacturer of screw-machine products, automobile starting cranks and drag links.

The Morse Chain Company, Ithaca, N. Y., has opened two additional branch offices, one at 1402 Lexington build-

ing, Baltimore, Md., in charge of E. R. Morse, and the other at 302 Harrison building, Philadelphia, Pa., in charge of M. H. Rodda.

The Hydraulic Press Manufacturing Company, Mt. Gilead, Ohio, has opened a branch office in the Mutual Life building, Buffalo, N. Y., in charge of R. K. Havlicek, who for some time has represented the company as a sales engineer, with office at Mt. Gilead.

W. W. Williams, general manager of the Reading Iron Company, Reading, Pa., has been elected vice-president in charge of sales and operation and J. M. Callen, second vice-president, has been elected vice-president in charge of purchases and distribution of materials.

The Curtain Supply Company, Chicago, has taken over the manufacture and sale of the steam and electric railway devices formerly made and sold by the Forsyth Brothers Company, Harvey, Ill., and is increasing the capacity of its plant to care for the additional business.

Joseph R. Beatty, manager of the Fairbanks Company, Boston, died recently at his home in Newtonville, Mass. He was born in Philadelphia January 27, 1863. His connection with the Fairbanks Company started in 1896 in Philadelphia, and in 1902 he went to Boston as manager there.

The Black & Decker Manufacturing Company, Towson Heights, Baltimore, Md., announces the establishment of a permanent office and showroom at 1436 South Michigan avenue, Chicago, Ill. This office will be in charge of R. G. Ames, whose territory has been extended to cover the middle West.

Leslie R. Pyle, whose election to the vice-presidency of the Locomotive Firebox Company, with headquarters at Chicago, was announced in *Railway Mechanical Engineer* for April, was born at Cleveland, Ohio, on June 7, 1880. He entered railway service on February 6, 1906, as a locomotive fireman on the Minneapolis, St. Paul & Sault Ste. Marie. On June 1, 1909, he became an engineman, and from 1912 to 1913 was traveling fireman. On May 1, 1913, he was appointed a fuel supervisor, which position he retained until July 1, 1918, when he was appointed supervisor of the Fuel Conservation Section, Division of Operation, United States Railroad Administration. This position he retained until March 1, 1920, when he was elected to the vice-presidency of the Locomotive Firebox Company.

L. R. Pyle

The Oxweld Acetylene Company, Newark, N. J., has taken over the manufacture of the Prest-O-Lite welding and cutting equipment. This apparatus, with certain refinements of design, is now being manufactured by the Oxweld Acetylene Company under the name of Eveready welding and cutting outfits.

Joseph T. Ryerson & Son, Chicago, have made an arrangement with the Camden Iron Works, Camden, N. J., to become the selling representatives of that company, which is engaged in manufacturing hydraulic tools, centrifugal

pumps, cast iron pipe and fittings, gas holders and kindred products.

The Triangle Equipment Company has been organized to deal in railway and contractors' equipment of all descriptions, with headquarters in the Munsey building, Washington, D. C. The officers are W. P. Gleason, president; Richard E. Lewis, manager, both previously with the Pennsylvania Railroad, and Anderson Allyn, treasurer, formerly with the director of sales, War Department.

J. C. Little, mechanical engineer of the Chicago & North Western, with headquarters at Chicago, has resigned to enter the service of H. G. Doran & Co., Chicago representatives of the Schaefer Equipment Company, the Clark Car Company and the Mason Tanking Company, all of Pittsburgh, Pa.; Benson & Co., New York, and the Rivet Cutting Gun Company, Cincinnati, Ohio. Mr. Little was born at Dunkirk, N. Y., on August 20, 1871, and was educated at Stanford University, Palo Alto, Cal. He began railway work with the Brooks Locomotive Works, now a part of the American Locomotive Company.

J. C. Little

In March, 1903, he went to St. Paul, Minn., as a draftsman for the Northern Pacific, and later was promoted to chief draftsman. In 1904 he was appointed chief draftsman on the Louisville & Nashville, with headquarters at Louisville, Ky., retaining that position until September, 1906, when he was appointed mechanical engineer of the Chicago & North Western.

The New Britain Machine Company, New Britain, Conn., announces the election of the following officers: F. G. Platt, chairman of the board of directors; H. H. Pease, president and treasurer; A. Buol, vice-president; S. T. Goss, vice-president; C. R. Hare, vice-president; R. S. Brown, Secretary; and H. E. Erwin, assistant secretary.

D. Gleisan, manager, industrial bearings division of the Hyatt Roller Bearing Company, New York, announces that its offices have been removed from 1 Madison avenue to 100 West Forty-first street, New York, where much larger headquarters have been secured for the advertising, sales and engineering department of the division.

The Thomas Spacing Machine Company, Pittsburgh, Pa., has opened an office in Philadelphia, at 57 Transportation building. G. L. Bohannon will be in charge of this office and will handle the company's entire line of equipment. He was formerly chief engineer and assistant general manager of the Youngstown Steel Car Company.

The Rickert-Shafer Company, Erie, Pa., announces the following appointments: A. A. Shafer, secretary and general manager; C. W. Howard, formerly with the General Electric Company, general sales manager; A. J. Patterson, formerly with the Crucible Steel Company, general superintendent; and George Paterson, production manager.

Charles A. Coons resigned as secretary and treasurer of the Paxton-Mitchell Company, Omaha, Neb., on April 1, to enter the railway supply business in Omaha. Mr. Coons was connected with the Paxton-Mitchell Company for the last 14 years and prior to that time was in the motive power and car department of the Union Pacific for 20 years.

The Campbell-Howard Machine Company, formerly the Sherbrooke Iron Works, Ltd., Sherbrooke, Que., has been purchased by G. L. Bourne and F. A. Schaff, respectively president and vice-president of the Locomotive Superheater Company, New York. The company's plant will be utilized partially to manufacture railway supplies for Canadian railroads.

John N. Derby, vice-president of Manning, Maxwell & Moore, Inc., New York, died at his home in Greenwich, Conn., on March 29. Mr. Derby was born 53 years ago.

J. N. Derby

He was a graduate of the University of Michigan, and in 1888 organized the Hayden & Derby Manufacturing Company in the state of Michigan. About 30 years ago he became associated with Manning, Maxwell & Moore, and the Hayden & Derby Manufacturing Company was afterwards absorbed by the United Injector Company. Mr. Derby, at the time Manning, Maxwell & Moore was incorporated, was made first vice-president, director and a member

of the executive committee. His special end of the business was looking after the brass department, managing the sales of the Ashcroft Manufacturing Company, the Consolidated Safety Valve Company, and the Hancock Inspirator Company, and looking after the general railroad trade covering these lines. He was the inventor of the Metropolitan injector used on steam engines and locomotives.

The Koppel Car Repair Company has been organized recently as a subsidiary of the Koppel Industrial Car & Equipment Company, Koppel, Pa. The new company has a shop located on the property of the parent organization and is turning out four repaired cars a day and has capacity for the dismantling and preparing for repair of about 30 cars at one time.

The Hulson Grate Company, Keokuk, Iowa, has been incorporated for the purposes of manufacturing and selling engine and locomotive appliances and devices. The amount of capital stock authorized is \$100,000 and the incorporators and officers include: A. W. Hulson, president; B. D. Streeter, vice-president; J. W. Hulson, secretary-treasurer; C. R. Joy, and W. M. Hogle.

N. M. Barker, master mechanic of the Copper Range Railroad, at Houghton, Mich., has resigned to become mechanical superintendent of the American Automatic Connector Company, Cleveland, Ohio. He will have supervision of the manufacturing and installation of the connector this company is placing on the market, which is designed to automatically connect steam and air hose on freight and passenger cars.

The American Steam Conveyor Corporation, Chicago, announces the appointment of the Kon-Wald Engineering Company, Mutual Life building, Buffalo, N. Y., as its representative in Buffalo and western New York. F. A. Konzelman is manager of that company. The Brooks-Fisher Company, Chandler building, Atlanta, Ga., has been appointed southeastern representative. This company was organized early last summer to carry on a business of manufacturers, agents and contractors.

C. H. Martin and Gustav Schirmer, of the Whiting Foundry Equipment Company, Harvey, Ill., after serving for several years in its estimating and sales department at the main office, have been respectively transferred to its Pittsburgh and Detroit offices, to take up the duties of sales engineers. Both men are experienced engineers and are thoroughly familiar with the design and construction of cranes and foundry equipment.

H. U. Morton, vice-president of the Dunbar Manufacturing Company, Chicago, has been elected president of that company, succeeding Thomas Dunbar, who has resigned. The Dunbar Manufacturing Company, during the period of the war, was engaged entirely on war work and received an award for distinguished service for quantity production of artillery ammunition bodies. The company has resumed the manufacture and sale of its various railway appliances and is also in position to manufacture steel doors for cars, steel pressings, stampings and drawn steel shades.

George H. Snyder has been appointed sales engineer, with headquarters at St. Paul, Minn., of the American Steel Foundries, Chicago. He entered the service of the store department of the Minneapolis, St. Paul & Sault Ste. Marie as a clerk in 1905, and was promoted to chief clerk of the same department in 1909. He remained in that position until August 1, 1911, when he was transferred to the mechanical department and served as chief clerk under T. A. Fogue, general mechanical superintendent, until his new appointment with the American Steel Foundries.

Karl J. Eklund, general manager of Mudge & Co., has been elected vice-president in charge of sales and service. In this capacity Mr. Eklund will also have charge of western sales

K. J. Eklund

for the Pilliod Company, Swanton, Ohio, and the Chambers, Lyle Company. Mr. Eklund was born on July 8, 1884, and entered railroad service as a blacksmith's helper in the shops of the Boston & Maine. After three years as an apprentice machinist he was employed on various railroads as a journeyman machinist. In 1908 he returned to the Boston & Maine as machinist and foreman in the Keene, N. H., shops, and on March 1, 1910, he became connected

with the Pilliod Company as a valve gear inspector. On February 1, 1915, he was appointed assistant to the president of the Pilliod Company, with headquarters at New York City. He occupied this position until April 1, 1917, when he was appointed assistant to the president of Mudge & Co., Chicago, and served in this capacity until his appointment as general manager on March 1, 1918.

The properties of the Southern Locomotive Valve Gear Company, Knoxville, Tenn., have been purchased by General L. D. Tyson (former president) and associates, and reorganized as the Southern Valve Gear Company, with ample capital and facilities to take care of any and all demands for Southern valve gears and Brown power reverse gears. The officers of the new company are: General L. D. Tyson, president; Forrest W. Andrews, vice-president; William Whaley, general manager, and H. P. Strayer, secretary. The headquarters of the new company are at Knoxville.

At the annual meeting of the Pratt & Letchworth Company, Buffalo, N. Y., on March 2, changes were made in the officers of the company as follows: John C. Bradley, who for a number of years has been president of the company, was elected chairman of the board of directors; John H. Bradley, general manager, was elected vice-president and general manager; Franklin D. Locke, vice-president, was elected first vice-president; John P. Williams, who has been manager of sales, was elected second vice-president in charge of sales, and Willis M. Edwards was re-elected secretary and treasurer.

The leather belting plant and business of the Edward R. Ladew Company, Inc., Glen Cove, N. Y., has been bought by the Graton & Knight Manufacturing Company, Worcester, Mass., oak leather tanners and makers of leather belting. The operations of the Ladew organization will be continued as heretofore by the new owners. The plant of the Ladew Company comprises 10 modern buildings, with a floor area of 14 acres, and employs more than 600 persons. The company has branches in Boston, New York, Newark, Philadelphia, Charlotte, Pittsburgh, Cleveland and Chicago and distributors in all principal cities.

Walter H. Lovekin, for the past two years assistant to the president of the Locomotive Feed Water Heater Company, New York, has been elected vice-president and treasurer.

He was born in Philadelphia, Pa., and received his education at the Haverford Preparatory School, Haverford, Pa., and Princeton University. After leaving Princeton he was employed for a time by the Logan Trust Company, Philadelphia, Pa., and by the Bell Telephone Company as a traffic inspector. He subsequently joined the Philadelphia Bureau of Municipal Research as a member of the staff, and served in this capacity for two and a half years. During this time he made detailed studies and surveys of various civic problems. After leaving this work he went with the R. J. Crozier Company, Philadelphia, as a salesman, handling railway, mill and mine supplies. On June 1, 1916, when the Locomotive Feed Water Heater Company was but two and a half months old, he entered its service, a few months later being appointed assistant to the vice-president, and in December, 1917, he was appointed assistant to the president, which position he held until his recent election as vice-president and treasurer. For the past two and a half years Mr. Lovekin, in addition to his other duties, has been in charge of the company's activities in the marine field. This involved the manufacture and delivery of feed water heaters, evaporators, boiler feed pumps, distillers and oil coolers for more than 550 ships built or building for the U. S. Shipping Board, Emergency Fleet Corporation. As vice-president he will continue in charge of the marine department and will be in charge of all sales and sales matters for the company, in addition to his duties as treasurer.

Charles C. Phelps has recently become associated with the Uehling Instrument Company, 71 Broadway, New York, combustion engineers and manufacturers of CO₂ recording equipment and other fuel economy apparatus. Mr. Phelps

W. H. Lovekin

is devoting most of his attention to research work in connection with the efficient combustion of fuel oil in boiler furnaces. He graduated from Stevens Institute of Technology with the degree of mechanical engineer and has since been studying power plant problems, having been for five years associated with the Ingersoll-Rand Company, New York. Mr. Phelps is an associate member of the American Society of Mechanical Engineers.

Edward Wray has associated himself with Railway Materials as managing editor, with headquarters in Chicago. Mr. Wray was formerly managing editor and publisher of the *Railway Electrical Engineer* from its first issue in 1909 to 1916, when the magazine was purchased by the Simmons-Boardman Publishing Company, publishers of the *Railway Mechanical Engineer*. Mr. Wray continued his connection with the magazine as business manager, and later became associated with the Sangamo Electric Company, Springfield, Ill., as assistant general manager. He received his education at the University of Wisconsin, graduating in

E. Wray

1905, and received the degree of electrical engineer in 1906, following a year of special work devoted exclusively to the investigation of all of the various systems of lighting steam railroad cars by electricity. In carrying out this work Mr. Wray had the assistance of 10 electrical students of the senior class at the university. Mr. Wray is a member of the American Institute of Electrical Engineers, associated member of the Railway Storekeepers' Association and the Association of Railway Electrical Engineers, and has been treasurer of the Railway Electrical Supply Manufacturers' Association since its organization in 1909. *Railway Materials*, the paper of which Mr. Wray is now managing editor, was until recently known as the *Railway Storekeeper*. It is published by the former Railway Storekeepers' Association, now known as Section VI Purchases and Stores, of the American Railroad Association.

R. Rivett, supervisor of car repairs for the United States Railroad Administration, with headquarters at Washington, D. C., resigned on March 1 to enter the service of the Oxweld Railroad Service Company, New York, as district manager, with headquarters at Chicago. Mr. Rivett was formerly connected with the Chicago, Burlington & Quincy, entering the service of that railroad in 1881, and resigning in 1902 as general car foreman. Subsequently he was appointed general car inspector for the Union Pacific. He left the service of the latter road in 1910 to become general car inspector for the Illinois Central. In 1918 he became supervisor of car repairs for the Railroad Administration.

The Metal & Thermit Corporation, New York, in order to take care of its increasing business in the New England states and in Canada, has appointed James G. McCarty manager of its Canadian branch, with headquarters at Toronto, Ont., and has transferred Robert L. Browne from its New York office to Boston, Mass., where he will have charge of all sales in the New England states. Mr. McCarty was graduated from Stevens Institute of Technology in 1906, and became affiliated with the Metal & Thermit Corpora-

tion in 1909. He has had a wide and varied experience with all phases of the Thermit process and has represented the company in many sections of the United States and Canada. Mr. Browne has been associated with the New York office since 1917.

R. T. Walsh, general sales manager of the Sullivan Machinery Company, Chicago, for the past eight years, has been appointed vice-president in charge of sales and has also been elected a director. Mr. Walsh was born in Massachusetts and received his education at Worcester Polytechnic Institute, graduating in 1900. He entered the service of the Sullivan Machinery Company at Claremont, N. H., and after several months was assigned to the western branch of the company at Denver, Col., as a salesman. In 1906 he was appointed Pacific coast manager, with headquarters at San Francisco, Cal. He was promoted to European sales manager, with headquarters at London, Eng., five years later, and in 1913 he was appointed general sales manager, which position he held until his recent promotion.

Locomotive Stoker Company

A. C. Deverell has resigned as superintendent of motive power of the Great Northern, at St. Paul, Minn., to become western sales manager of the Locomotive Stoker Company, Pittsburgh, Pa., with office at Chicago. He was born in Montreal, Que., and after attending the public schools of that city began his career in the shops of the Grand Trunk at Montreal. He went west in 1895, and while performing

He was foreman at Albert Lea, in charge of locomotive and car work from March, 1899, to February 1903, but during the last two years of this period served as traveling fireman and extra locomotive engineman and pilot. In February, 1903, he was made traveling engineer and inspector for the American Locomotive Company, resigning in September, 1904, to take service as general foreman on the Delaware, Lackawanna & Western, at Elmira, N. Y., serving until November, 1905. He was appointed a master mechanic on the Buffalo, Rochester & Pittsburgh, in November, 1905, remaining in that position until January, 1908. From January, 1908, to August, 1909, he was occupied in special work for the superintendent of motive power, and was made special representative and assistant to general manager in August, 1909, remaining in that work until June, 1918. He was then appointed supervisor for the Allegheny region, Fuel Conservation Section, U. S. Railroad Administration, which position he recently resigned.

J. J. Byrne has been appointed district representative of the Locomotive Stoker Company, with his headquarters at new offices opened in Washington, D. C. He was born in Cincinnati, Ohio, and attended the public schools of that city and Delaware, Ohio. He entered railroad service in 1903, in the Cleveland, Cincinnati, Chicago & St. Louis shops at Delaware, as machinist apprentice. After completing his apprenticeship, he entered the service of the New York Central Lines as machinist in the Collinwood shops. He remained in the employ of the New York Central until 1909, when he left to accept a position as mechanical ex-

some special work for Samuel Hill, president of the Eastern Minnesota Railway, came to the notice of the late James J. Hill, who appointed him superintendent of the freight car shops at St. Cloud, Minn. He was promoted to superintendent of the St. Paul locomotive and passenger car shops, the largest shops on the Great Northern system, employing approximately 19,000 men. He subsequently became assistant superintendent of motive power and later served as superintendent of motive power until his recent appointment as western sales manager of the Locomotive Stoker Company.

H. C. Woodbridge has resigned as supervisor of the Fuel Conservation Section of the U. S. Railroad Administration to enter the service of the Locomotive Stoker Company as representative, with headquarters at Pittsburgh, Pa. He was born on October 7, 1874. He worked in the machine shops at Chatham, N. Y., and was extra fireman on the Lebanon Springs Railroad during 1891 and 1892. In 1897, he graduated as mechanical engineer from Cornell University. From June, 1897, to March, 1899, he worked as a machinist in the Minneapolis & St. Louis shops at Minneapolis, Minn.

pert with the Locomotive Stoker Company. In 1917 he was appointed representative with headquarters in New York, and the following year was transferred to the southern territory, with headquarters at Roanoke, Va. Later in the year he was located in Richmond, Va., in charge of the Locomotive Stoker Company's office at that place.

The general offices of the Chicago Pneumatic Tool Company on March 31 were removed from Chicago to the Chicago Pneumatic building, a new 10-story structure erected for the exclusive use of the company, at 6 East Forty-fourth street, New York. The move was accomplished without appreciable interruption to business over the week-end. Arrangements, carefully made in advance, made possible the jump of the organization across half of the continent without interference to the normal routine of business except for a brief period. The Chicago district sales branch, previously in the Fisher building, has been moved to new quarters at 300 North Michigan boulevard. The Chicago service

branch, formerly at 521 South Dearborn street, has been consolidated with the sales branch, at the new address, and both departments are under the direction of J. L. Canby, district manager.

W. G. Walsh, notice of whose election as vice-president of the Galena Signal Oil Company, Franklin, Pa., with headquarters at Chicago, was announced in last month's issue, began railway service as an apprentice in the machine shops of the old Cleveland, Cincinnati, Chicago & Indianapolis, at Cleveland, Ohio. On the completion of his apprenticeship, he became a machinist on the Cincinnati, New Orleans & Texas Pacific at Somerset, Ky., and prior to 1890 was successively locomotive fireman, engineman and general mechanical instructor. In 1890 he was promoted to master mechanic of the Louisville division, with headquarters at Louisville, Ky., which position he retained until 1900, when he resigned to become mechanical expert for the Galena Signal Oil Company. In 1910 he was promoted to resident manager, with headquarters at Chicago, which position he retained until his recent election to the vice-presidency.

W. W. Frazier has recently been appointed assistant superintendent of the tube works of the Reading Iron Company, Reading, Pa. He began work as a draftsman and for four years served at the Loraine plant of the National Tube Company, both in the construction of its pipe mills and in the operating department. Later he served in an engineering capacity in the rearrangement of the pipe mills of the La Belle Iron Works and then went with the Youngstown Sheet & Tube Company, where for seven years he was first in the engineering department and later was general foreman of its tube mills. He was chief engineer of the A. M. Byers Company for one year, leaving that company to become assistant chief engineer at the government plant that was being built for the Ordnance Department by the U. S. Steel Corporation at Neville Island. When the armistice stopped work on this plant he went with the Bethlehem Steel Company, at Sparrows Point, as assistant chief engineer and recently became associated with the Reading Iron Company as assistant superintendent of its tube works.

J. S. Lemley, who for the past five years has been general sales manager of the G. F. Cotter Supply Company, Houston, Texas, has left that company to become associated with and a partner of W. D. Jenkins, Dallas, Texas, representative of manufacturers of railway equipment and supplies, with principal office at Dallas and offices also at Houston and New Orleans, La. Mr. Lemley will have full charge of all mechanical matters. He served on the Baltimore & Ohio in 1898 as a locomotive engineman and a short time later was promoted to trainmaster. After serving in this capacity for two years he went to the mechanical department of the Chicago, Milwaukee & St. Paul. Two years later he was appointed general supervisor of locomotive operation of the Baltimore & Ohio South-Western and the Cincinnati, Hamilton & Dayton, with headquarters at Cincinnati. After serving in that capacity for two years he went to the mechanical department of the Texas & Pacific, remaining with that road until July 1, 1915, when he became associated with the G. F. Cotter Supply Company. C. E. Naylor, who has been associated with Mr. Jenkins since 1916, and formerly served on the Texas & Pacific and the International & Great Northern in the mechanical and traffic departments, is in charge of the Houston office. R. L. Irwin is in charge of the New Orleans territory. Mr. Irwin was formerly purchasing agent of the Texas & Pacific, and during federal control of the railroads was purchasing agent of the lines under the jurisdiction of F. G. Pettibone as federal manager at Dallas, Tex. J. K. Bagley, formerly with the Texas & Pacific as chief clerk in the purchasing department, is in charge of the New Orleans office.

TRADE PUBLICATIONS

UNION FITTINGS.—The E. M. Dart Manufacturing Company, Providence, R. I., has issued its 1920 catalogue (S) of unions and flanges, with illustrations, prices and schedules showing sizes, dimensions, weights, etc.

TIME ZONES.—The Metal & Thermit Corporation, New York, is distributing a large map and calendar for 1920, showing railroad time zones in the United States and Canada and illustrating a number of interesting repairs made with Thermit welding.

LOCOMOTIVE CHART.—The Angus Sinclair Company, New York, has recently prepared a chart of a Pacific type locomotive showing a longitudinal cross section and a rear view of the interior of the cab. The detail parts are numbered and the names are given in a list printed on the sheet.

AIR COMPRESSORS.—The National Compressed Air Machinery Company, San Francisco, Cal., has published a bulletin, No. 20, describing the construction of a vertical type air compressor and containing a table of dimensions and specifications of the various models built by this company.

CRANES.—The Whiting Foundry Equipment Company, Harvey, Ill., has issued a new edition of its crane catalogue, designated as catalogue No. 151, containing 80 pages, 6 in. by 9 in., with a great many illustrations. Cranes of all types are represented and detailed information is given concerning them.

VISE FOR PNEUMATIC DRILLS.—A four-page circular has been issued by the Independent Pneumatic Tool Company, Chicago, describing a new universal vise for pneumatic drills, the purpose of which is to firmly clamp and hold the drill in accessible positions while repairs, assembling and testing are done. Illustrations show the detail parts of the vise and how to use it.

POWER HAMMERS.—A belt-driven and a motor-driven power hammer are described in a 16-page booklet published by Beaudry & Co., Inc., Boston, Mass. Both types are manufactured in various sizes and are described in detail, with tables showing sizes and dimensions. All the individual parts are illustrated and numbered for convenience when ordering.

SOME REMARKS FROM DAN MCGANN.—Under this title the Walworth Manufacturing Company, Boston, Mass., has issued a folder containing a short poem in which Dan McGann declares his adherence to the principles of Americanism in the vigorous language of the shop. The folder, which is suitable for use as a poster, has already had a wide circulation in industrial plants.

CONSTITUTION OF THE UNITED STATES.—The Clark Equipment Company, Buchanan, Mich., has published an attractive booklet containing a reproduction of the Constitution of the United States and all amendments. It is illustrated with pen portraits of notable American Presidents by W. M. Young. This is a booklet which every American would be glad to have, and will be mailed on request.

AIR COMPRESSORS.—Bulletin 75-U of the Sullivan Machinery Company, Chicago, describes in considerable detail the Sullivan tandem compound Corliss steam driven air compressors, class "WC", which are available in unit capacities of from 1,000 to 3,150 cu. ft. of free air a minute. Photographs accompanying the text show installations of the Sullivan Corliss compressors and indicate the range of service which they are performing.

BULLARD

BULLARDIZE
YOUR PRODUCTION

To Bullardize your production is to obtain the greatest profit per man, per machine, per minute, and per inch of floor space.

Teeming One of Our Electric Crucible Furnaces Ludlum Electric Crucible Steel

Every visitor to our plant tarries awhile here—for it is very fascinating to watch a Ludlum Electric Crucible Furnace teeming into the ladle.

The Ludlum Electric Crucible Furnace was developed entirely by us, to meet our own individual requirements. It produces unexcelled quality of absolutely controlled analysis.

Do you realize that the majority of twist drill and milling cutter manufacturers in America are using Ludlum Steels?

Among the Ludlum "Consistently Uniform" Brands are

MOHAWK EXTRA

High Speed Steel

ALBANY

Alloy Tool Steel

HURON

Alloy Die Steel

YUMA

Chrome Magnet Steel

POMPTON

Carbon Tool Steel

ONEIDA

Oil Hardening Tool Steel

TETON

Ball Bearing Steel

SEMINOLE

"Fool Proof" Chisel Steel

LUDLUM STEEL COMPANY

General Offices and Works
WATERVLIIET, N. Y.

This LUDLUM Text Book is a complete treatise on the various tool steels. It describes the correct method of forging, hardening, tempering, annealing. It contains accurate calculation tables and other valuable information. Just ask us for it and it's yours, free.

"Prompt shipment from warehouse stock at Watervliet, N. Y., or Detroit, Mich., handled through our District Offices."

Strictly a Business Proposition

THE June conventions at Atlantic City this year will surpass all records in every respect. Under the new form of organization and with the war excitement behind us, it has been possible to give much better attention to the preparation of the reports and to the rounding out of the program. The action of the Railroad Administration last year in encouraging a more general attendance of mechanical men met with cordial approval; moreover a large number of executive officers visited the meetings and looked over the big exhibit and were so greatly impressed that they indicated that they would encourage an even larger attendance this year. The exhibit space for the coming convention has been extended to include the balcony in the large main entrance hall on the pier and will cover almost 100,000 sq. ft. Even then a large number of concerns have had to be turned away because of lack of space.

Section VI, Purchases and Stores, of the American Railroad Association, will meet on the last three days of the mechanical convention, and this will not only add largely to the number of railway men in attendance, but in these three days and the preceding Saturday the exhibit will be crowded. As usual the Association of Railway Electrical Engineers will meet on Monday of the second week of the convention.

The expense of arranging for this big meeting and sending the delegates to Atlantic City will mount into hundreds of thousands of dollars. The *Railway Mechanical Engineer* believes that this expenditure is very much worth while, but it would like to take this opportunity of offering a few suggestions with a view to helping to get the greatest possible return from this great expenditure.

In the first place, what is such a convention for? Is it not primarily for intensive educational work coupled with the great inspiration which accompanies attendance at such meetings? This, if rightly directed, will result in more economical and efficient operation; if it does not show concrete results in this respect it will be extremely difficult to justify the continuation of the conventions on the present scale.

Who should go to the conventions? Every responsible mechanical department officer who can be spared from the job for part or all of the time, and particularly the ambitious, energetic young men who in a few years will be in line to fill more responsible positions. Many a young man has found himself at these meetings and has gone back to his job with an enlarged vision of the possibilities before him and a will to do. The railroads, particularly in these days, can ill afford to miss an opportunity of enlisting the enthusiastic support of young men of this kind. Any expense involved in their attendance at the Atlantic City conventions will be insignificant compared to the possible returns.

What should be the attitude of the delegates to the con-

ventions? No railroad executive will authorize the investment of money unless it will bring a good return—at least 10 per cent—on the investment. The railroad man going to the conventions should realize that in order to make the trip worth while he will have to insure a good return on the cost of sending him to the meetings and paying his salary and expenses during that time. It is simply a cold-blooded business proposition and it adds an element of real sport to the occasion.

How can one get the greatest possible good from the convention? No one really attains any worth-while end unless he has a goal or definite objective constantly before him. It is not enough that a man go to the convention with good intentions and a disposition to profit by his attendance. He must go with the very definite object in his mind of trying to improve some troublesome condition or of increasing the efficient working of some part of the work in which he is interested. He may get help in solving his particular problem or problems in the convention hall; or it may be in interviewing men engaged in similar effort on other roads; or it may be in studying some of the exhibits, or in talking matters over with the engineers or service men of the railway supply companies; it may even be in conversations on the trains going to and from the convention. Too many men get into a rut and keep their noses so close to the grindstone that they miss big opportunities of profiting by the experiences of others. There are many striking examples on record of men who have been forcefully kicked out of the rut by mixing with their fellows at the conventions.

Frank McManamy took the bull by the horns last year and through the regional directors asked all of the mechanical men to report on the things which they heard or saw at the mechanical conventions which could be applied to advantage on their own roads. Mr. McManamy's idea was to encourage the men to use their time to the best possible advantage and therefore justify the Railroad Administration in arranging for a record-breaking convention. Unfortunately there was more or less misunderstanding as to the purpose of these reports. It is to be hoped that this year the heads of the mechanical departments will instruct their assistants as to just what features each individual should specialize upon, and then that the reports be made either at a staff meeting on the return home or to the head of the department in writing.

A written report need not be formal, nor need it be long or complicated. What is the thing you recommend? Why? Where should it be applied? What will its installation cost? What are its limitations?

These questions may refer to a device or a method or practice of some sort. Fifty words may cover your recommendations, but you must put them up in such a way as to sell the idea to your boss. Give the definite data which will help him to draw a conclusion; otherwise the matter may be laid aside and forgotten.

Just a word to the supplymen. Those exhibits which are most novel, or which are so arranged as to attract special attention to the special advantages of the particular device or equipment, will of course make the most distinct impression. Have your best service men and engineering talent on hand to talk to the man who is right from the firing line

and is anxious to talk practical details. If you do not know the men, don't judge too much by appearances. The big boss is not always the most prepossessing in appearance or the best dressed man in the group. Some supplymen will tell you this, to their great embarrassment.

The supplyman must remember also that mechanical officers are looking for real dollars and cents arguments as to the value of a device. It is to your interest to see that they get the right kind of concrete data to incorporate in their reports.

The Atlantic City conventions offer wonderful opportunities for big gains in the more efficient and economical administration of the mechanical department. What part will you have in securing better results?

An Inevitable Comparison

MANY railroad mechanics and foremen are now contrasting their present condition with the situation in industrial shops. Industrial enterprises have generally been exceedingly prosperous in recent years and have found it possible to attract many experienced railroad men from the mechanical department. Under the circumstances it is inevitable that comparisons should be drawn at this time which are not always favorable to the railroad. The basis for this comparison is, however, not always a sound one. Industrial activity is now at its height and young men particularly are apt to overlook the possibility of a reversal in this state of affairs that will cause many of the less stable industrial shops to discontinue operations. Transportation has had its reversals, but it has always kept functioning and has tided the greater portion of its employees over years of severe business depression.

A further analysis of the situation will probably show that the policy of promotion on merit versus pull is, if anything, more generally observed by the railroads than industrial concerns. Except where industrials are organized on a very large scale the relation between ownership and operation is more intimate, from which it follows that promotion to executive positions is more often awarded to relatives and close personal friends of the owners than could possibly be the case on the railroads.

The operation of an industrial shop is generally more highly specialized than is the case with the typical railroad shop. This in itself appeals to many men, who prefer an even volume of routine work to the usual variety and emergency character of railroad work. The material situation is easily controlled in a factory manufacturing a single article and industrial shops generally appear to be in better running order than the average railroad shop, but is it to the advantage of the young man to be employed in a shop where every operation is planned for him and initiative is entirely in the hands of a production engineer? It might be advantageous for the railroad shop if a higher degree of scientific management prevailed, but it is doubtful if this would tend to develop the same energetic and resourceful men on whom the railroads are today so dependent.

There are other factors in this comparison between railroad and industrial shops that are less in favor of the railroads and with respect to which there is room for improvement. Industrial shops are generally housed in better structures, they are better lighted, better heated, better arranged and more sanitary than the average railroad shop. They are often located in the very center of a residential section that is admirably suited to the requirements of the employees, whereas railroad shops, if not located in some untenable district adjoining railroad yards, are so far removed from any habitable center that the shop train must be resorted to in order to transport the employees to and from work. While location may be governed by conditions over which the railroads have little control, there is no cor-

responding reason why some of the community and welfare work promoted by industrial concerns cannot be undertaken by the railroads. To what extent are the railroads studying the personnel of their employees? How many mechanical executives have ever studied their labor turnover as compared with that of an adjoining railroad or a neighboring industry? The railroads are now in a position to do as much if not more for their employees, particularly the young men, as any industry, and this is a fact that must be made apparent to every one of their employees if the railroads expect to keep abreast of industrial development.

The Business Viewpoint

THE extent to which mechanical executives can contribute towards making the operation of their railroads profitable depends entirely upon the extent to which they acquire the business viewpoint. Probably the best way to get this viewpoint is to consider how a new device, a new shop, or a new method would affect your pocketbook if you were the proprietor of the company. If you were convinced that a new device will save its cost in fuel and wages within a period of two or three years, would you not try very hard to make its operation a success? On the other hand, if it was determined that a new shop would cost one million dollars to build would you not want to be very sure that it would effect a real saving of at least one hundred thousand dollars per year before you would commit your company to this investment at the current rates of interest? How many mechanical men appreciate the fact that an increase in the material stock of a million dollars costs the railroad at least seventy thousand dollars a year? Possibly you would scan material requisitions more rigidly than the purchasing agent if your income depended on the company's annual surplus.

Have mechanical executives lived up to their opportunities; have they grasped the business viewpoint? Have the recommendations of the mechanical department always condemned unprofitable investments in mechanical equipment and fought for profitable expenditures, or has this question been left to the decision of a higher executive?

No official on the railroad has a greater opportunity to make the operation of his property profitable than the mechanical superintendent; no official has a better claim to executive rank; and, provided he acquires the business viewpoint, no official will advance more rapidly in authority over the operation of the railroad.

Stresses in Locomotive Running Gear

IT is the general practice in designing locomotive running gear parts to allow a large factor of safety even with stresses based on safe values for carbon steel having low elastic limit and ultimate strength. The design of these parts is largely empirical; and while on large modern locomotives the parts are extremely heavy, due to the low stresses employed, very few roads have made any serious attempt to reduce the weight of rods and pins by the use of high grade materials. On account of the excessive weight of these parts many locomotives built in recent years are very difficult to maintain. While the boiler proportions are excellent and the operating results generally satisfactory, the design of the machinery from an engineering standpoint is a reproach to the mechanical officers.

The time has come to get out of the rut and to take a step forward. Alloy steels have been used on some roads with excellent results and more work should be done in developing their use, but the prejudice against the general use of a new material may retard the general introduction of alloy steels. There is no reason why higher stresses should not be used

in designing carbon steel parts, as it is possible to increase the strength of carbon steel forgings to a remarkable extent by proper working and heat treatment. A series of tests recently conducted on a forging seven inches square showed that by proper treatment the yield point could be raised from 45,000 lb. to 87,000 lb. per square inch. The resistance to impact showed a remarkable increase, the average energy required to fracture the bar when quenched and drawn at the proper temperature being more than seven times as great as that which caused fracture in the material as forged from the ingot.

The low elastic limit and ultimate strength in large forgings are no doubt due to the tendency to work the larger sizes at higher temperatures than the smaller sections. The direct result of this practice is to reduce the ability of the larger parts to withstand shock. The proper forging temperature of approximately 1,000 deg. C. or 1,830 deg. F. renders the material sufficiently plastic for thorough working by forging presses, though the power hammer is effective only in breaking up the crystallization near the surface.

A better appreciation of the effect of mechanical working on the properties of carbon steel would be secured if the impact tests were more generally used. Thorough working does not greatly alter the values obtained from tension tests, but impact tests show the remarkable increase in the ability to withstand shocks. The reduction of the dynamic augment is one of the most important questions now confronting the locomotive designer. The reduction in the weight of parts through improved design has probably been carried as far as is practicable. It is to be hoped that measures will be taken to lighten locomotive parts through the use of material which will withstand higher unit stresses.

Conventions and Committees

WITH several important conventions over and the June conventions at Atlantic City just ahead, it might be well to take account of some of the objects and a few of the results to be derived from any convention of railway mechanical men. The conventions must not only advance the knowledge of mechanical progress in transportation, but must broaden the outlook on all mechanical matters. The fact that a new method or a new device is making good on a single road should inspire mechanical men all over the country to ignore the immediate objections or the added complications and make this new method or device a success for the ultimate welfare of their own road. That a paper on train loading presented before a recent convention should be made the subject for discussion at a staff meeting of division officers is in itself proof that the good effect of conventions is far-reaching. No good paper on such matters as train loading, feedwater heating, improved shop methods or shop tools should become mere literature after the convention is over; it should be considered at the earliest possible staff meeting and continue to be a live topic on every railroad.

The task of writing the reports that go before these conventions should be taken very seriously by the committees to whom they are entrusted as they are a guide to individual practice on many roads. Every report represents an opportunity to effect an improvement in existing practice—sometimes a very great improvement—and the failure of a committee to put its best effort into a report or to cover the latest and most improved practice is an opportunity lost. There is need generally for a better working agreement between committee members and the chairman, so that the burden of preparing a report will be more evenly distributed and the report will more nearly represent the individual opinion of each member. It is suggested that this situation might be improved by permitting a chairman some part in selecting the other members of his committee.

Reports should be written so that they can be applied to specific problems, and will present the most advanced and dependable information on the subject to those who are seeking instruction. Committee members cannot know how much help their reports give to others, because they may have a far wider distribution than they suspect. But if the report is written to be used, it will be used. It may be discussed not only at staff meetings but at directors' meetings, and should be constructed accordingly.

Car Wheel Grinding

MACHINES for grinding the treads of car wheels have been used in the railway shops of this country about fifteen years, but in spite of this long test period which demonstrated their value, these machines have by no means come into general use. In fact one of the leading manufacturers, has made only eleven installations of car wheel grinding machines in steam railway shops in the United States. There are three possible explanations for this situation: (1) the possibilities in car wheel grinding are not realized; (2) the railroads are not in a financial position to purchase machines; or, (3) the practice is not as successful as some authorities claim. The last explanation is refuted by an article in the present issue which shows how long it takes to grind car wheels, what kind of wheels should be ground and the resultant saving effected. It is hoped that this article will convince many mechanical department men, hitherto sceptical on the subject.

Most of the car wheel grinding done in the past has been confined to chilled cast iron wheels with flat spots developed in the treads due to sliding. Provided a wheel is not otherwise defective experience has shown it is practicable to remove flat spots up to $3\frac{1}{2}$ in. long by grinding. Owing to the fact that the depth of chill in a chilled cast iron wheel is limited, it is obvious that a longer flat spot can be ground out of a new than a worn wheel without going through the chill. The condition of the flange is also a limiting factor. According to the article referred to a substantial saving is effected by reclaiming chilled cast iron wheels by grinding.

All machine tools including car wheel grinders have increased in cost approximately 100 per cent in the past four years and it is plainly shown in the article that in order to pay heavy interest and depreciation charges the machine must be kept busy as much as possible. The maximum saving per pair of wheels is dependent on the ability to keep the machine in operation eight hours a day. Inasmuch as the average time of grinding a pair of cast iron wheels is 38 minutes, this requirement would mean that any railway shop receiving as many as 12 or 13 pair of slid flat wheels a day can well afford the installation of a grinding machine.

But the field for car wheel grinding is not limited to the reclamation of flat cast iron freight car wheels. Chilled cast iron wheels are now used to a considerable extent on light suburban passenger cars. While these wheels are cast approximately true in the foundry, there is always a possibility of the tread being slightly eccentric with regard to the journal, due to improper boring. Furthermore, the slight raised chill marks on the tread produce a whirring sound at high speeds and may cause increased wear on the rail. These are serious objections and have been overcome by grinding the new wheels before going into service. This insures a smooth riding car, without objectionable noises. In addition, a greater mileage is claimed for the ground wheel. The grinding of new chilled cast iron wheels has been extended also to wheels used on box cars, refrigerators, stock cars and caboose cars.

Car wheels with wrought steel tires are usually turned when the treads or flanges become worn and this practice is undoubtedly advisable and indeed necessary if the wheels are badly worn. For wheels that are only slightly worn,

however, a cut must be taken sufficiently deep to get under the hard surface skin on the tread. With a grinding machine, it is possible to true up this tread, taking off just enough metal to remove the imperfection and the grinding method in this case results in a considerable saving of surface metal. Experience shows that it pays to grind wrought steel tired wheels that are slightly worn, the limiting feature being the amount of flange wear.

With the cast steel car wheel, the arguments in favor of grinding stand out more prominently than ever and especially in the case of wheels with treads of hard alloy steel. These wheels can be reclaimed by grinding should flat spots develop, but they are first ground before being put in service. The time required to grind new wheels is, on the average, twenty minutes which includes ten minutes required to set a pair of wheels in the machine. At that rate, it would be possible to grind twenty-four pair of wheels in an eight-hour day.

In view of the manifest advantages of having smooth, round car wheel treads concentric with the journals, it would seem a paying proposition to install machines for grinding new car wheels and there is no important railway shop that could not keep the grinder busy either on new wheels or reclaiming old ones.

Breakage of Locomotive Cylinders

THE breakage of cylinders on locomotives is among the troubles which have increased with the introduction of large engines. The universal use of piston valves may be partly responsible for this trouble, or it may be due in part to the proportionately smaller clearance volume on large cylinders. The major share of the blame, however, may be ascribed to improper cylinder cock rigging. Little attention is paid to the maintenance of these parts; the long connecting pipes are often not properly supported, and if there is more than the usual amount of resistance to the movement of the lever the connecting rods buckle or the levers bend, with the result that the cylinder cocks do not open. The inevitable result is frequent breakage of valve and cylinder packing rings, if the cylinder itself is not fractured.

Several devices are now in use which operate the cylinder cocks either by compressed air or by the action of the pressure within the cylinder. It would seem that a more general application of such devices would be justified in cases where difficulty is experienced in applying a satisfactory design of manually operated cylinder cock rigging. It must be realized that such changes are open to objection on the basis that they introduce additional complication on the locomotive, but the cost of new cylinders or of welding broken cylinders, together with the loss of service from the locomotive, is so serious that there should be no question as to the desirability of using such devices where excessive cylinder breakage is experienced.

Adequate Reinforcing for Cars

SO many expensive mistakes have been made in building cars of light and unserviceable construction that it should not be necessary to call attention to the ultimate economy of substantial design, particularly in underframes. The new cars built at the present time are in most cases amply strong, yet some roads which insist that new cars should be of more than average strength are still applying underframe reinforcement that is entirely inadequate for present day service. Experience has demonstrated that where a steel center sill is added to a wooden underframe, the steel member takes practically the entire force of the buffing shocks. The wooden sills assist in carrying the load, but they offer little resistance to end thrust and have only a slight tendency to prevent buckling unless the construction is designed with special regard for this detail. Therefore, any steel center sill applied to wooden

cars should have sufficient strength, when considered as a column, to withstand the shocks it will receive in service without depending upon the other parts of the underframe to help carry the end load.

The argument is sometimes advanced that a weak car is not worth reinforcing with a heavy center sill. A heavy center sill costs but little more than a light one and the cost of application will in most cases be practically the same. The slight additional investment is therefore a minor consideration, for the heavy steel member will take the shocks which would otherwise rack the body of the car and soon make it necessary to repair or rebuild it. The problem of underframe design has been discussed by the Committee on Car Construction of the Master Car Builders' Association and if its recommendations were applied also to the design of reinforcing, many costly errors would be avoided.

The Responsibility of the Unions

FOR several months practically every railroad in the United States has been working under the wage agreement negotiated by the Railroad Administration, which provides for a written notice of any desired changes in the wages or working conditions. During that time numerous "unauthorized" strikes have been called by local officers of the unions without giving notice to the railroads. The adjustment of wages is now in the hands of the Federal Wage Board and provision has been made for the orderly settlement of disputes, yet there are still numerous "walkouts," and in every case the responsibility for getting the men back to work comes back to the railroad officers. It is not an uncommon occurrence for a superintendent of motive power to waste several days each month trying to settle strikes at isolated points on the road.

The present wage agreement is a contract in which one party, the railroad, apparently assumes all the responsibilities while the other party, the labor federation, exacts as much as possible but promises nothing in return. The unions give no assurance that their members will return a fair day's work for a day's pay and when the contract is violated by a strike, disclaim responsibility by stating that it is unauthorized. If the railroad violates its agreement the union secures redress by striking; when the union violates the contract there is no redress for the railroad. Is it not time that this one-sided arrangement was changed? Should not the responsibility of the labor organizations be more clearly defined and some provision made for holding them to the fulfillment of the obligations of their contract?

NEW BOOKS

Steam Power. By Hirshfeld & Ulbricht, 420 pages, 7½ in. by 5 in. Bound in cloth. Published by John Wiley & Sons, Inc., New York. This book may be described as a text book, a handbook and a thoroughly up to date treatise on steam power and power plant practice. The subject matter has been more fully dealt with in hand books and previous volumes on the same text, but in this book the attempt has been made to collect within a single volume such parts of the subject as would be needed by engineers whose work does not require an intimate knowledge of thermodynamic principles. The book, however, does give a very good conception of the subject of entropy and other theoretical aspects of steam power. The authors have made frequent use of charts in connection with the subject of fuel and combustion problems, and the descriptions of boilers and boiler appliances as well as steam engines, turbines and auxiliary apparatus is very complete.

This book was designed primarily as a text book, but will answer very well as a reference book for engineers interested in modern power plant practice and the operation of railway stationary power plants.

What Do You Think?

WHAT do you think is the most instructive, the most interesting or the most readable article in this issue? If you would tell the editor occasionally it would help make the *Railway Mechanical Engineer* a more valuable as well as a more readable paper. What editorial in this issue appeals to you most? If you know of a subject that ought to be brought home to the mechanical department, don't hesitate to suggest it for editorial comment.

This issue contains a description of a new up-to-date engine terminal that has replaced inadequate facilities and equalized the length of operating divisions on the Michigan Central. What do you think about the engine terminal situation? Are not larger and better equipped engine terminals more urgently needed than almost any other improvement on your railroad?

If your chief interest is in shop practice you will find numerous articles that should be of particular interest in this issue. The broader aspects of the machine tool situation are discussed on page 359. The methods used by the Canadian Pacific for locating weak points in the shop are described in the article on "Taking Up the Slack in Production." If you are having trouble with your tools you may find some helpful suggestions in the description of the Fort Wayne heat treating plant.

Stationary plants have been among the most neglected parts of railroad shops. The article by Mr. Rogers tells how capacity may be increased and fuel consumption lowered.

How much money could your road save by making small parts in quantities and sending them out over the system? It is an important question and one which the article entitled *Automatic Machines an Aid to Production* should help you to answer.

Are you availing yourself of the economies that can be effected by grinding car wheels? If not you should read carefully the description of that practice in this issue. The Shop Equipment section contains descriptions of many shop appliances and you may find

there just the machine you are looking for. If you are interested in reducing shop costs it is suggested that you read Mr. Armstrong's plea for more thorough cost accounting.

Do you know that Germany has more locomotives now than before the war? No article contributed to the popular magazines or daily press gives you a better insight into the state of affairs in Germany than the article on the railroad situation in that country appearing in this issue. Railroad welfare is so intimately identified with national welfare that Mr. Thayer's account of these railroads may convince you that Germany is getting back on her feet.

Is it not interesting to note "feed water heat surface" listed along with other dimensions shown for the new German locomotives as though it were a factor to which we have always been accustomed? Don't you think that if feed water heaters are a success in Germany we ought to make a success of them in this country?

There seems to be a general impression that the Latin-American countries are behind the times, but you will probably reach a different conclusion after reading the article on South America by Mr. Risque. In this issue he tells of some interesting methods used to overcome difficult operating conditions in the Andes.

Even though you are not an air brake expert, you will want to study the report of the Air Brake convention. The paper on the steam consumption of locomotive auxiliaries is particularly important, as it shows a serious source of fuel waste that is often overlooked.

The author of the story "How the Master Mechanic Increased Production," has some unusual ideas about handling men which every foreman or executive should consider carefully.

In conclusion, don't neglect the comments on articles published in previous issues which are found on the next four pages. They represent the views of men who are right on the firing line and may give you a new viewpoint on some important questions.

COMMUNICATIONS

EDITORIAL ON SERVICE OF SUPPLY DRAWS FIRE

TO THE EDITOR:

I have a copy of the *Railway Mechanical Engineer* for May, 1920, and have read the editorial on page 256 entitled Service of Supply.

I do not think you have handled this on a broad enough basis; you admit that delays for material offer one of the best excuses for not getting power out, and later state that the supply department can usually produce a convincing argument as to savings made by reduction in material cost, which the shop superintendent cannot prove in dollars and cents. There is no room for argument as regards the desirability of having the very thing you need at your disposal at all times, but if this theory were to be put into practice, nine-tenths of our business institutions, as well as our railroads, would be in receivership. Such a proposition is not justified, except in case of war, and it is open to criticism even then.

Business must be conducted on the basis of its credit; if it spends more than its receipts and has not sufficient capital at its back to carry it through, it is insolvent. A railroad's operation must necessarily be based on its earnings, plus its borrowing power. Materials use approximately 35 per cent of a railroad's gross earnings; therefore, a railroad's expenditures must be guided largely by its earnings. Labor is fixed by law; the only savings that can be made in materials is its better utilization.

The problem of supply is one that embraces not only the demands, but is one of finance; every dollar tied up in material is unliquid capital and bears the regular interest rate, plus deterioration and obsolescence. Shop superintendents and shop foremen are interested only in their particular work and have no conception of the problem of supply, taking in, as it must, the entire requirements of the railroad.

A railway may need double tracking, passing tracks, yard facilities, round houses, shop extensions, shop tools, and many other things, but that is not given as an excuse for not moving trains, or even moving them economically. *The real measure of an organization or individual is what they are able to accomplish with the facilities at their command.* One may see locomotives and cars by the scores lying over for months for repairs, and at the same time hear the cry of work being delayed for material. There is no such thing as work on a railroad being delayed for material; there may be some particular work delayed for material, but there is always more work on a railroad than there is money or men to do, so that the losses experienced by lack of material are largely a myth on most of our railroads and in practically all of our shops.

Nothing in the above is to be construed as justifying the lack of sufficient material to protect the operations of the railroad; that is vital, but it can be set down as a fact, that the railroad that has the most material, has the least material available. The best operated railroads are the ones that have the least money tied up in materials, and an organization which is capable of meeting emergencies and utilizing everything they have to the best advantage.

GENERAL PURCHASING AGENT.

HANDHOLES VS. WASHOUT PLUGS

GREAT FALLS, MONT.

TO THE EDITOR:

I have read with much interest the article by Mr. Lipetz on above subject in your April issue. If we adopted handholes on our locomotives, as used in Russia, they would be the source of much trouble and worry to our mechanical departments.

While Mr. Lipetz's argument in regard to safety might be true, yet accidents that happen in this country from washout plugs blowing out can usually be traced to carelessness on the part of the boiler washer, either in leaving a loose plug, or putting the plug in cross threaded.

I have just returned from Siberia after over two years' experience on the railroads there, and have seen considerable of the type of handholes described. The new American Decapods in that country are all equipped with these handholes; it is surely anything but ornamental to see the "horse shoe" clamps used on this device sticking out around side sheets and throat sheets. Boiler washers have to exercise great care in replacing the lead gaskets—have to feel inside to see that the seats are properly cleaned before replacing the cover, which process consumes much time.

I have also seen not a little trouble due to leakage, and when that happens in a country where bad water is practically unknown, what might happen in our bad water districts here where we get such an accumulation of scale and dirt. I am afraid the seats would be a continual source of trouble. Mechanical men are quite familiar with the troubles that our belly plate gaskets give and I don't believe they want more gaskets on the boiler. The initial expense of application is heavy compared to washout plugs, also the expense of continually renewing the gaskets.

It would be a step backward to replace washout plugs with handholes.

Great Northern Railway.

WOMAN IN RAILWAY SHOPS

BILLERICA, Mass.

TO THE EDITOR:

During the war, many women were employed in railway shops not only as clerks, sweepers and cleaners, but as machine operators in the tool rooms and machine departments. A long enough period has now elapsed to get a perspective of the results accomplished by this introduction of women into railway work and what the possibilities may be for the future. Most of the shop managements replaced their women employees with men as fast as the latter became available after the armistice was signed and men only are now employed. In some shops, however, women have been retained as sweepers and, in a few cases, operate machines such as lathes, shapers, milling machines, etc. The total number of women employees retained for shop work, however, is very small and it is doubtful if their number will ever be materially increased except in case of another emergency.

An analysis of the motives causing women to enter the railway shop service, shows why so small a number kept their positions after the war was over. In some cases, women took up the work to help support their families while the

men were in the military service. In other cases, the work was undertaken because a desire for notoriety and the opportunity to meet men. In still other cases, the principal motive was a liking for machinery and mechanical work.

Women who entered railway service for either of the two first motives could be classed as temporary employees and would remain only until they were married or the head of the family returned. The latter class, however, included a few women who became very efficient and skillful machine operators. They attended strictly to business, wasted no time and were more quick and dexterous than men in operating the lighter machines. These women were most welcome in any machine shop but, unfortunately, they formed such a small minority of the total number as to be practically negligible. On the road with which I am familiar only two out of several women employees developed into really skillful machine operators.

FOREMAN.

SPECIFICATIONS FOR SOFT METAL BEARINGS

WASHINGTON, D. C.

TO THE EDITOR:

With reference to the article on soft metal bearings appearing in the May issue of the *Railway Mechanical Engineer* and your editorial on page 256 of the same issue. The first part of the article by Mr. Frank is an excellent presentation of the general principles of bearing metals.

The article next mentions the specifications of the American Society for Testing Materials. The committee which prepared them included railroad representation. The three bronzes specified are approximately similar to three of those specified by the American Railroad Association and the Railroad Administration. The assignment of two of these alloys to specific bearings is peculiarly different, however. The two last mentioned organizations use a harder metal for locomotive driving bearings than for car bearings, while the A.S.T.M. reverses this arrangement. From the standpoint of cool running (the most important feature of the operation of bearings) either alloy may ordinarily be used for either purpose. The driving bearings are, however, subjected to greater shocks, therefore from this standpoint should be of the harder metal. It is to be understood that the term is only relative. Both alloys are softer than the No. 1 bronze.

The reader of Mr. Frank's article may possibly gain a partially erroneous idea of the Railroad Administration specifications used for car and locomotive bearings during the war. They were not new ones. They were essentially the existing standards of the Master Car Builders' and Master Mechanics' Associations. The only changes made in the bronze were (1), a reduction in the minimum phosphorus in phosphor bronze for locomotives, from 0.7 to 0.4, on account of the scarcity of phosphorus, and (2) an increase in the maximum impurities in locomotive bronze to two per cent. (Before the U. S. R. A. specifications could be issued, a part of the locomotive hard bronze was ordered without phosphorus.)

The four U. S. R. A. bronzes were therefore as follows:

	Car Bearings	Locomotive Bearings		
		Phosphor Bronze	Medium Bronze	Soft Bronze
Copper, max	65	82	77	65
Copper, min	4	8	7	4
Tin, min	24-30	8-13	14-20	20-33
Lead	3	0.4-1.0	0.2-0.6	2
Phosphorus		2	2	2
Impurities, max				

The car bearings were the largest item. Without stopping to make an accurate survey, it is safe to say that the average composition of the bearings actually furnished was much nearer 24 per cent lead, the minimum limit than 30 per cent, the maximum. The soft bronze was used only for hub liners and constituted only a small percentage of the

total requirements for bearings. The composition, 65 copper, 5 tin, and 30 lead, can therefore hardly be called typical or average. The average lead would be much lower.

It is generally considered that the lead is the "anti-friction" constituent of the alloy and should be as high as possible, consistent with sufficient strength of the bearing and satisfactory foundry work.

It is agreed that temperature of pouring both bronze and lining metal is very important.

The writer does not agree that "little can be expected, at present, from inspection tests." Chemical composition within proper limits, with respect to both the essential constituents as well as the individual impurities, must be secured, and can be determined fully only by analysis. The other important detail in inspection is the surface appearance and the fineness and uniformity of grain and the soundness and homogeneity of the metal as shown by the fracture. In the hands of an experienced inspector these give much information on the conditions of manufacture. Microscopic examination is very useful in special investigations. Compression tests are not generally employed in routine inspections except for bearings carrying very high pressures.

H. E. SMITH,

Engineer of Tests, New York Central Lines, West (Asst. Manager Inspection and Test Section U. S. R. R. Administration).

I. A. LEARNS SOME THINGS ABOUT "PASSING THE BUCK"

TO THE EDITOR:

While at Westport, become necessary learn why dirty gage glasses not replaced. Hon. M.M. agree are not done because Stkpr. do not furnish. Sustain M.M. veracity, becomes bounden duty interview aforesaid Stkpr.

In pursuit of elusive person, Jap Detector at end directed clean cut young man in blue overall suit, and blue shirt with soft collar, who are bossing unloading gang. Sympathy are elicited by distressed appearance and learn he are helpless victim of Wage Board and U.S.R.R.A. "pass the buck."

Indicating Hon. self, he declaim that it are impossible eat, live and clothe on large salary Stkpr. U.S.R.R.A. have looked out for ash-pit shoveler, Bolsheviki, shop cobblers, all but Stkpr. Result he are responsible for keeping down R.R. H.C.L., but so busy making \$1 buy \$2 pork and beans, potatoes and other necessities keep body and soul, Hon. self and family, he are distraught.

G. F. who run back shop with help S. S. are laden with 275 iron men per month while Stkpr charged with \$5,000.-000 stock each year get 210 and storehouse foreman 115. Surprising intelligence are Hon. Stkpr in blue overalls. With majestic sweep of hand he declaim, other Stkpr's get \$150, some \$175.

Jap detector become further initiated in mysteries forbidden storehouse and find paper pins, also engine fireboxes in yard. Impressed by magnitude Stkpr job. Advised impossible keep man, when road contractor bid high, also industry in town, which account for fact he are overlook unloading when Jap Detector discover him.

Breast filled with pity for distressed Stkpr; hesitate. It are bounden duty as Imperial Government detector to learn why gage glasses not forth coming. Assume commanding attitude and demand explanation, beating down rising pity. Stkpr. tearfull admit such are true, but he are crushed struggling with H.C.L. and problem beans. Storehouse Foreman have succumbed to struggle with 115 iron men. Chief Clerk have gone digging ditches account need clothes to cover naked form. Load of Stkpr. so heavy impossible carry. Result no gage glasses ordered until G.F. and Hon. M.M. announce glasses assume zero. Some time G.F. announce twelve year boy can run Storehouse better Stkpr. Stkpr. reply he are d—m well cognisant truth stated, but G.F. job insignificant

alongside Stkpr. job, and he had two year boy make better G.F. than present incumbance.

Stkpr. express great sorrow lack gage glasses and conclude "if Gage Glasses are so long come as promised wage boost, engine worn out when arrive." INO AMSURA.

THE SHOP WAGE AGREEMENT

NEW YORK.

TO THE EDITOR:

I am greatly interested in the invitation under "What Do You Think?" on page 191 of your April issue, to comment on Mr. McManamy's article in that issue on the Shop Agreement.

The shop committee idea was suggested by the Railroad Administration during the last few months of federal control and a number of the roads appointed such committees. Something might have been accomplished if the matter had been handled in the proper way. The difficulty lay in the manner in which the instructions were issued; i. e., to have the members selected by the regular shop committeemen. This, coupled to conditions that existed in the shops at the time, made the realizing of any good results very problematical.

Supplement No. 4 to General Order No. 27 was the first milestone and probably the worst one of the many things that were wished on us and which resulted in the tearing down of the structure of our organization. This placed all our mechanics—good, bad, and indifferent—on the same footing; prohibited rewarding merit in any manner; made our better mechanics dissatisfied in that they received the same wage as the incompetent workers; and in the cases of men who were working before as handymen and who were given full rated mechanics' pay under the application of this order, their status was in no wise improved—they were practically spoiled by receiving large sums as back pay.

Our former method of handling these handymen was surely much the best; they were advanced on the grade of work and in pay as they were worthy of advancement and in the course of time were promoted to full rated mechanics. This method gave the foreman an excellent opportunity to gain the workman's loyalty and co-operation, as the foreman in all cases was required to recommend and approve those selected for promotion. In fact the application of Supplement No. 4 took away from the supervisors almost entirely having anything to say as to wage, making the situation most difficult.

In the Eastern district where the demand for skilled mechanics has been so urgent during the last three or four years and the railroad wage rates considerably under those paid on the outside, the foreman already had his hands full trying to prosecute work through the shops with a large per cent of poorly skilled help. Loading him up with an instrument embodying all the hide-bound union conditions found in Supplement No. 4 certainly could not improve conditions and went a long way to increase the already burdensome and inefficient conditions.

The next important move was the order that no mechanics could be employed after July 25, 1918, without having had four years' experience as a mechanic. Many of us were compelled during the war to employ men with less than this amount of experience; they were put on as step-rate men. The road had to be kept going; men of long experience could not be obtained. After considerable time had elapsed all these men employed after July 25, 1918, were advanced to the full rate and given large back pay sums. This made our older men in point of service very much dissatisfied and unsettled and materially helped along the growing undesirable conditions. While these men were either reduced to helpers or helper apprentices, under this order, the rest of the men felt that they were not

titled to the back pay, and took the attitude that they should not have been employed in spite of the fact that we were forced to do so during the war period, these very same men claiming that they were intensely patriotic and yet it was impossible to get them to speed up their production.

The shopmen utterly failed in selecting the best from among themselves as their union officers and committeemen; men with absolutely no judgment or balance were selected in many instances. In some cases they were men who could not intelligently read an order and properly construe it. In some instances they gave out wrong interpretations to the members which resulted in many complex situations and much dissatisfaction. Many men were wrongly influenced so that they developed a grudge against the company. It was a foregone conclusion that committeemen selected for the shop committee by the regular union committee would not be the kind of men that would make up a committee worth while—one that would assist the men in charge of the shops in bettering conditions.

As to the National Agreement; while it is possible that there were some benefits derived from this agreement in certain districts in that it made conditions uniform, results generally were not the best. There are many rules in this agreement that unquestionably helped along our already burdensome conditions. Absolutely no differential rates whatever were allowed to the men in the machinist craft. The blacksmith and boilermakers were given differential rates for practically all the men who do the better class of work; the machinists as a result were much disturbed. The old axiom of treating all men fair and square seemed to be farthest removed from the intentions of many of the orders that were issued.

The rule requiring two mechanics operating a long stroke hammer capable of driving $\frac{5}{8}$ -inch rivets or staybolts, or larger, was surely unnecessary. Two men cannot possibly work on a hammer driving staybolts. Also the rule requiring that sufficient help be furnished mechanics operating compound motors; our men tapping staybolt holes have for years done this work with a light one-man motor with no hardships whatever.

GENERAL FOREMAN.

INCREASED MILEAGE FROM ASSIGNED ENGINES

TAUNTON, Mass.

TO THE EDITOR:

The return of one of the heavy passenger locomotives to the repair shops of one of our eastern roads, after having handled one of the crack limited trains on that road for over a year between shopping and making a total of about 115,000 miles, when other locomotives of the same class cannot show an equal performance, gives rise to an interesting situation.

It seems, however, that this locomotive in question is handled by two engineers, on different days, of course, and the writer believes that this case and other citations to follow will go far to prove that the best way and the most economical way is to give a man an engine and let him keep it.

Another instance. On a certain eastern run of 57 miles, the death of the engineer caused a new man to be placed on this run. Several men and several locomotives were tried and finally a suitable locomotive was placed on this run, but the men had trouble handling the locomotive, and about every other trip a visit to the repair shops was necessary. About the first of March a certain careful engineer was placed on this run, and a man who was interested in his machine. The result has been that since that date this locomotive has not missed a trip, nor can one minute's delay be charged up to this locomotive. This engineer has this locomotive all the time and no other.

A certain north and south line in the Middle Atlantic

States has adopted this policy of assigning a locomotive to an engineer and with admirable results. I believe that one of our eastern trunk lines on its two most famous and fast trains uses this same policy.

Very well. If our railroad managers find it a wise policy to adopt this scheme for their fast runs, why not carry it a step farther and make it universal, at least for passenger trains. There no doubt would be too many difficulties to overcome in freight service.

Anyone who has overheard a group of enginemen talk after having completed their runs might well draw a conclusion that there was not a single locomotive on the road fit for service. Can you blame them? Any man who has to run about a half a dozen different locomotives in as many days is going to lose interest in his machine. What does he care if someone else is going to have her on the next trip? Give a man a rickety engine, and you will have a rickety engineer. Assign him a certain machine, let him study it, know the "kinks," what she will and what she won't do, and your runner will be making his schedules and saving money in the long end, and the average man, unless he is a hog, will take care of his machine—it is human nature to do so.

The old excuse will be that "It can't be done." It can be done if the managers are so minded. Another excuse—"the locomotive mileage will be reduced." Doubtless it will be *per month*, but how about it in the long run, say 12 or 18 months? Every time a locomotive goes into the shops for a thorough overhauling, it costs money, and the railroad is deprived of earning money from that locomotive every day it is in the shops, and this holds true when the locomotives undergo slight repairs, and in these days of high labor and material costs this item seems worthy of attention.

If a locomotive, assigned to one of our fast limited trains, in charge of two careful men, alternately, can produce 20 per cent more mileage between shopping, then figure out the proportionate reduction of shop charges and increase in train mileage, were every other locomotive of this class thus treated. Is it worth it? I think so!

CHAS. E. FISHER.

INFLATED TONNAGE RATINGS

CLEVELAND, Ohio.

TO THE EDITOR:

Mr. Mounce's article on practical freight train loading, which appeared in the May issue of the *Railway Mechanical Engineer*, is a very able presentation of the main problems involved in determining the tonnage that can be most expeditiously and economically handled. The article is in fact a very clear exposition of the principles involved and it would be difficult to take exception to the figures submitted by Mr. Mounce except from the standpoint of the practical means by which it is proposed to arrive at the desired results.

I have in mind particularly the effect which an inflated tonnage rating will have on the engine and train crews hauling these trains. It is well known that a great many locomotive engineers are governed in handling trains very largely by the tonnage which they are told that they are hauling. It is not always possible to explain to these men the significance of adjusted tonnage ratings and that a rating which takes into consideration a car factor added to every car in the train is to a certain extent fictitious.

If a car factor is added to the weight of every car in the train in an attempt to equalize the variable resistance of cars of different weights, the result is an apparent tonnage always in excess of the actual tonnage. The result of this is that the apparent difference in tonnage between trains consisting entirely of heavily loaded cars and trains comprising only empty cars is exaggerated and we have what might be termed an inflated tonnage rating. This does not affect the scientific correctness with which the train is loaded, but it manifestly affects the psychological effect on the locomotive en-

gineer who is hauling the train. This psychological effect may not be confined to the locomotive engineer, but may have an equally potent effect on the division superintendent who has not taken the pains to reason out the theory of adjusted ratings nor to carefully study their effect. The fact that the average tonnage per train handled over his division actually averaged considerably less than the average adjusted rating assigned to the division may have a very dampening effect on his enthusiasm for making a good tonnage showing.

We have to depend so much on paper or statistical showings to obtain results in modern railroading that it is well to respect any method that will sustain interest in making a good showing and discourage any procedure that tends to break down a favorable report even if the underlying motive is sound. Therefore, while it is highly important that all tonnage ratings be adjusted, it is equally important that any method employed, for securing these adjustments be such that the average car factor be as small as possible. The same ultimate loading, for instance, may be obtained by adding a certain car factor to every car in the train, dependent on its weight, as by adding a much smaller factor to some cars in the train and subtracting a factor from other cars. In the latter case it is obvious that the total adjusted rating of the train will be a much lower figure than in the first case, although the actual weight of the train will be the same. In fact, if the average weight of all freight cars to be handled were approximately the same and this weight were known, the adjusted rating could be made to equal the actual rating, or if this were a permanent condition there would be no necessity for adjusted ratings.

The point is that in determining adjusted ratings for any freight division, an attempt should be made to determine the approximate average weight of cars usually handled over the division in each direction. This weight then should be adopted as, what might be termed, the neutral weight and all car factors to be employed in the adjusted rating should be based on this weight. To all cars below this so-called neutral weight a car factor should be added, increasing in amount as the weight of the car diminished; while from all cars exceeding this neutral weight a proportionate car factor should be subtracted. Unless there is great variation in average weights of cars handled in a single direction over a certain division the adjusted rating can be determined in the manner above outlined, so that the adjusted rating assigned to freight trains will not vary greatly from the actual weight of these trains. The actual weight of trains and the total tonnage hauled over a division will theoretically be no greater with adjusted ratings corrected so as to approximate actual tonnage than with adjusted ratings computed in the manner outlined by Mr. Mounce, but the practical results obtained from a tonnage standpoint will be much improved, due to the fact that there is a much better understanding among all concerned in the movement of trains as to the actual tonnage handled by each train.

Under the arrangement outlined by Mr. Mounce it may happen that the adjusted tonnage where principally empty cars are being handled is 500 tons in excess of the actual tonnage. If this adjusted tonnage were corrected on the basis of the average weight of cars handled, which in this case would take into consideration the preponderance of empty cars moved, it would probably not vary more than one hundred tons from the actual tonnage. Practical men know the great value of having a system that does not confuse those to whom its execution is entrusted. The adjusted tonnage rating should conform to this rule and while retaining all the advantages to be secured from the equalization of car resistances must be exceedingly simple in its application and should not involve results which are not clearly understood by all concerned in its application.

L. GREENLEAF.

Superheater Freight Locomotives of the G-10 Type for the Prussian-Hessian Railway. The First Locomotive Built by Krupps.

THE RAILWAY SITUATION IN GERMANY

Shortage of Locomotives the Limiting Factor. Output of Labor Greatly Decreased

BY ROBERT E. THAYER

European Editor of the Railway Mechanical Engineer

THE aftermath of the war in Germany has been much more severe than perhaps was anticipated at the end of the war. The new government, formed after the revolution, was made up of men of little experience in the governing of a nation the size of Germany and as a result there has been a constant state of unrest, dissatisfaction and no co-ordination of effort. With the bolshevistic seed fairly well germinated, it was doubly hard to get the nation back on

of 3,800,000,000 marks, and in 1919, this rose to 4,600,000,000 marks. For 1920, it is anticipated that the figures will be considerably higher than this, for during that year some 2,000,000,000 marks were added to the railway pay roll. In order to meet this added expenditure, the rates up to the present time have been increased 600 per cent for freight and 700 per cent for passengers as compared with the pre-war rates.

Part of a Mixed Train on German Railway

a peace time rating. It has been the labor situation that has delayed the recuperation of this country. Not only has this been felt in the industries but on the railways.

Whereas before and during the war and up to the year 1917, the German railways earned sufficient revenue to pay a dividend to the state, the cost of materials and wages increased to such an extent in 1918 that there was a deficit

Serious Lack of Available Power

One of the greatest difficulties the German roads are experiencing today, is the lack of adequate locomotives. Notwithstanding the fact that Germany has a greater number of locomotives now than it had at the beginning of the war, it has been unable to keep them in repair on account of the extremely poor labor conditions. The low morale of the shop forces is almost unbelievable. It has been authoritatively stated that the output has decreased to from between 20 to 30 per cent of the pre-war output and at the same time wages have been increased from four to five times. Conditions were so bad during the early part of this winter, that it was found necessary to close some of the shops absolutely for a few weeks in order to teach the men a lesson. These shops were then reopened, each man being employed being required to work under conditions laid down by the railway shop managers. In some instances it was found that the men in the pattern shops were spending their time making toys which they sold later on the streets.

At the same time, due to the Peace Treaty, the German roads have lost 12 or about 16 per cent of their main repair shops and 3, or 23 per cent of their secondary repair shops. The conditions were so bad that in order to maintain any semblance of railway service repairs had to be put out on

contract to various industries that were in a position to handle such work. The equipment builders were requisitioned to take on repair work. Krupp's plant has repaired some 300 locomotives and has between 100 and 200 on hand for repair. The shipbuilders principally took on this work as the construction of ships has practically been brought to a standstill. The North German Lloyd is making a speciality of repairing cars and has handled some locomotive repairs.

Condition of Passenger Cars

The passenger equipment which is in operation may be said to be in good running condition, but its finish and upkeep is deplorable. The cars are dirty inside and out, there is practically no covering on any of the seats and the passengers have to be content to ride on cushions of dirty buckram which has become shiny with use. Many of the windows, which are of the drop sash type commonly used on the Continental roads, are in an inoperative condition due to the fact that the leather straps by which they are operated have been removed. This condition has been caused by the fact

Crowded Fourth Class Cars in Germany

that the seat coverings and the leather straps were cut away by passengers riding in the cars or thieves in the car yards, as there was a serious shortage of all leather and cloth goods.

Increase in Number of Locomotives Owned

While it is impossible to obtain detailed figures regarding the condition of locomotives for all of the German railways, the condition on the Prussian-Hessian system may be taken

LOCOMOTIVES ON THE PRUSSIAN-HESSIAN SYSTEM

Date	Locomotives owned	Percentage in bad order
1910.....	19,670	...
1911.....	20,187	...
1912.....	20,758	...
Aug. 1, 1914.....	21,882	19.5
Nov. 1, 1918.....	27,991	33.5
Mar. 30, 1919.....	22,538*	43.2
Sept. 3, 1919.....	23,248	44.6
Jan. 15, 1920.....	23,956	47.2
Feb. 12, 1920.....	23,224**	46.2

*After locomotives were delivered to the Allies.
 **After locomotives were delivered to Poland.
 Note Germany has still to deliver to the Allies under the terms of the armistice, 286 locomotives and 2,000 cars. The Prussian railways now have on order some 1,500 locomotives.

as indicative of the entire country. This system owns about 81 per cent of all the locomotives in Germany and on January 15 of this year over 47 per cent of its locomotives were out of service for repairs. In view of the further disturbances that have risen in Germany, this figure has probably in-

creased to over 50 per cent at the present time. Table I will show for the Prussian-Hessian system how the percentage of locomotives in bad order has increased.

This table also shows the increase in the number of locomotives on the Prussian-Hessian system from 1910 to February 12, of this year. It will be seen that before the armistice was signed (November 1, 1918) the Prussian system

Engine Storage Shed at Dusseldorf

had 27,991 locomotives as compared with 21,882 at the beginning of the war—an increase of 6,109. For all the roads in Germany the increase in locomotives owned was 6,648 (about 24 per cent) or a total of 34,570 on November 1, 1918. Of the locomotives turned over to the Allies under the terms of the armistice the Prussian system furnished about 83 per cent and this accounts for the drop between

Locomotive Equipped With Feedwater Heater

November 1, 1918, and March 30, 1919. There is a further drop between January 15 and February 12 of this year, of some 734 locomotives which is accounted for by the fact that at that time Germany was required to turn over a large number of locomotives to Poland.

The fact that Germany has more locomotives today than

she had before the war, regardless of the fact that she had already turned over 5,000 locomotives to the Allies, is accounted for by the intense locomotive production during the war. The locomotive manufacturing plants were called upon to do nothing else but build locomotives. Each plant was given a specific design to build and they turned them out in large numbers. It has been stated that during the war the number of locomotives built for the Prussian-Hessian system since 1913 averaged from 1,200 to 1,500 per year. Practically all of these locomotives were of a heavy type—for Germany—and of the most improved design.

New German Locomotives

Two of the latest designs built for the Prussian State are of the 2-8-0 and the 2-10-0 types, their principal dimensions

being shown in the accompanying table. Both of these engines have three cylinders. The inside cylinder is inclined and all three drive on the third axle. The right-hand driving crank follows the left at an angle of 120 deg. and the inside driving crank forms an angle of 152 deg. 21 min. with the right-hand outside crank and an angle of 107 deg. 39 min. with the left. These engines are equipped with the Schmidt superheater, brick arches and feed-water heaters. From trial performances it is found that the 2-8-0 locomotives were capable of hauling, on the level, 1,150 long tons at a speed of 40 m.p.h. while the 2-10-0 type was able to handle 1,400 long tons at the same speed. It is interesting to note that these engines are not compound and as a matter of fact with the present degree of refinement in superheating and feed-water heating, the engineers of the Prussian-Hessian have given up the idea of building any more compound locomotives.

Erecting Shop at Krupp

being shown in the accompanying table. Both of these engines have three cylinders. The inside cylinder is in-

PRINCIPAL DIMENSIONS OF NEW GERMAN LOCOMOTIVES:

Service	2-8-0 Type		2-10-0 type	
	Freight		Freight

Modernizing Railway Equipment

The coal situation in Germany has been disastrous to the railways as it has been to all of the other industries. It has always been the desire of the German railways to keep a three months' supply of coal in storage but at the present time it is difficult to get a supply for more than three or four days. Whereas in December, 1913, the Prussian-Hessian system held an average of 3,000,000 tons on hand, in February, 1920, the supply was only 100,000 tons which was hardly sufficient to last three days. In addition to the lack of it, coal has been of a very inferior quality and whereas the standard consumption was about 15 tons per 1,000 locomotive-kilometers it is now between 20 and 25 tons. Due to the severe shortage of lubricating oils, it has been necessary to extract the coal tar products of the coal which has thrown a large amount of coke on the railways for locomotive use.

Large Numbers of Feed Water Heaters Applied.—As in everything else, the price of coal has greatly increased. Be-

fore the war it was purchased for 12.5 marks per ton, but the railroads now have to pay 200 marks per ton. It will thus be seen that the increased cost of fuel has been a great factor in the increased operating costs. In view of this situation every attempt has been made to increase the efficiency of the locomotives. One means of doing this is by the application of feedwater heaters to all new locomotives with a plan in progress of applying them to all existing locomotives regardless of type or service. The success the German railways have had with the use of feedwater heaters has warranted this development. Whereas the thermal efficiency obtained is between 10 and 12 per cent there is a claim for an overall economy from 20 to 25 per cent.

This feedwater heater is known as the Knorr heater. It is of the tubular type taking exhaust steam from the cylinders and auxiliaries. The feedwater is forced through it by a pump located between the heater and the tank, which thus keeps the heater under boiler pressure. It has been estimated that these heaters will more than pay for themselves in the economy they produce under the present price of fuel within one year.

Freight Cars to be Equipped With Compressed Air Brakes.
—As indicated by the manner in which the German railways

Railway Entrance to Krupp Plant at Essen

are applying feedwater heaters to their locomotives, the officers are not hesitating to spend money in order to save money regardless of the fact that the roads are now being operated under such heavy deficits. In addition to improving the locomotives a very extensive program is being carried out in equipping the freight cars with Kunse-Knorr automatic air brakes. This is a compressed air brake which is standard on the Prussian system. A program involving the expenditure of 260,000,000 marks for this purpose has been started. One-third of the existing cars on the Prussian system, or about 175,000 cars, have been equipped with this brake and all new cars will be. By 1927 it is planned to have all freight cars on the Prussian system equipped. It has been estimated that at the end of 10 years a saving of 60,000,000 marks will be obtained, after having paid for the cost of the installation, as a result of the saving in wages of the train crews alone. This brake is of a relatively new design and operates on a principle similar to the Westinghouse brake.

The Continental roads before the war endeavored to come

to some arrangement for the application of a standard brake to all freight cars in order to facilitate the interchange of traffic. The problem at that time was whether the vacuum or compressed air brake should be used. Strangely enough the strongest advocates of the vacuum brake were to be found in Austria and even during the war, tests and negotiations were carried on between Austrian and the German roads in an attempt to settle the matter between them, but the unsatisfactory closing of the war to those countries prevented an agreement being reached. It appears by this extensive ap-

Passenger Car on Turntable Lead in the Station at Dusseldorf

plication of the power brakes to the Prussian roads, an attempt is being made to force the compressed air brake on all other nations in central Europe if they want to participate in the exchange of equipment with the German lines. While the use of automatic couplers is greatly desired to replace the screw couplings on freight cars, plans have not been developed sufficiently to permit of any definite action in this respect.

Car and Locomotive Building by Krupps

During the war the munition plants in Germany were developed and extended to a great degree and on the return to peace conditions these plants have been seeking to reconstruct and adapt their facilities to peace-time pursuits. The

Wheel Foundry at Krupp

greatest of these concerns is Krupps at Essen, and among other things, this company is planning to go into the construction of railway materials on a large scale. Whereas before the war 50 per cent of its income was derived from war materials, at the present time the demand for them is practically eliminated and the only war material Krupps intends to make will be to meet the requirements of Ger-

many's small army and navy. It is the intention of this company ultimately to be in a position to provide everything in the iron and steel line which goes to make up the construction of a railway. Before the war this company constructed a large amount of railway material, among which may be mentioned forged wheels and axles and springs of

construction of railway equipment as they are adjacent to the main line of the railway through Essen, which has several sidings leading into the plant. The plant itself is well equipped with cranes and much of the machinery used for the munition work can be used to good advantage for the present work. The accompanying diagram shows an out-

Milling Driving Boxes at Krupps.

Milling Rod at Krupps New Locomotive Works

all types. During the war it increased its wheel and axle capacity by 100 per cent and at the present time it is building locomotives and cars at the rate of 300 and 2,000 per year, respectively, working two shifts a day. Plans have

line of the shop and the manner in which the material is routed through it. It contains 19 bays of medium size running parallel with one another, all being equipped with electric driven cranes. It has been possible thus to bring

Armor Plate Mill for Rolling Plate and Locomotive Frames

been made to increase this capacity to 900 locomotives and 20,000 cars as the occasion demands.

The plant used for the manufacture of cars and locomotives is a new shop which was erected for the construction of guns and gun carriages and occupies a space of over 18 acres. These shops are particularly well located for the

under one roof all the necessary operations in the construction of cars and locomotives with the exception of die making, forgings, castings, axles and wheels, which are made in other shops of Krupps plant.

By referring to the diagram of the shop it will be seen that all materials for the construction of boilers, cranes and

Section Through the Five Bays in the Erecting Shop

Riveting the Boiler Barrel

Section Through Boiler Shop Showing Hydraulic Riveters

tenders, with the exception of such parts as are made in the shop itself, enter the shop by a lead from the railway at the southern or right hand side of the building. After passing

Testing Locomotive Boilers at Krupps

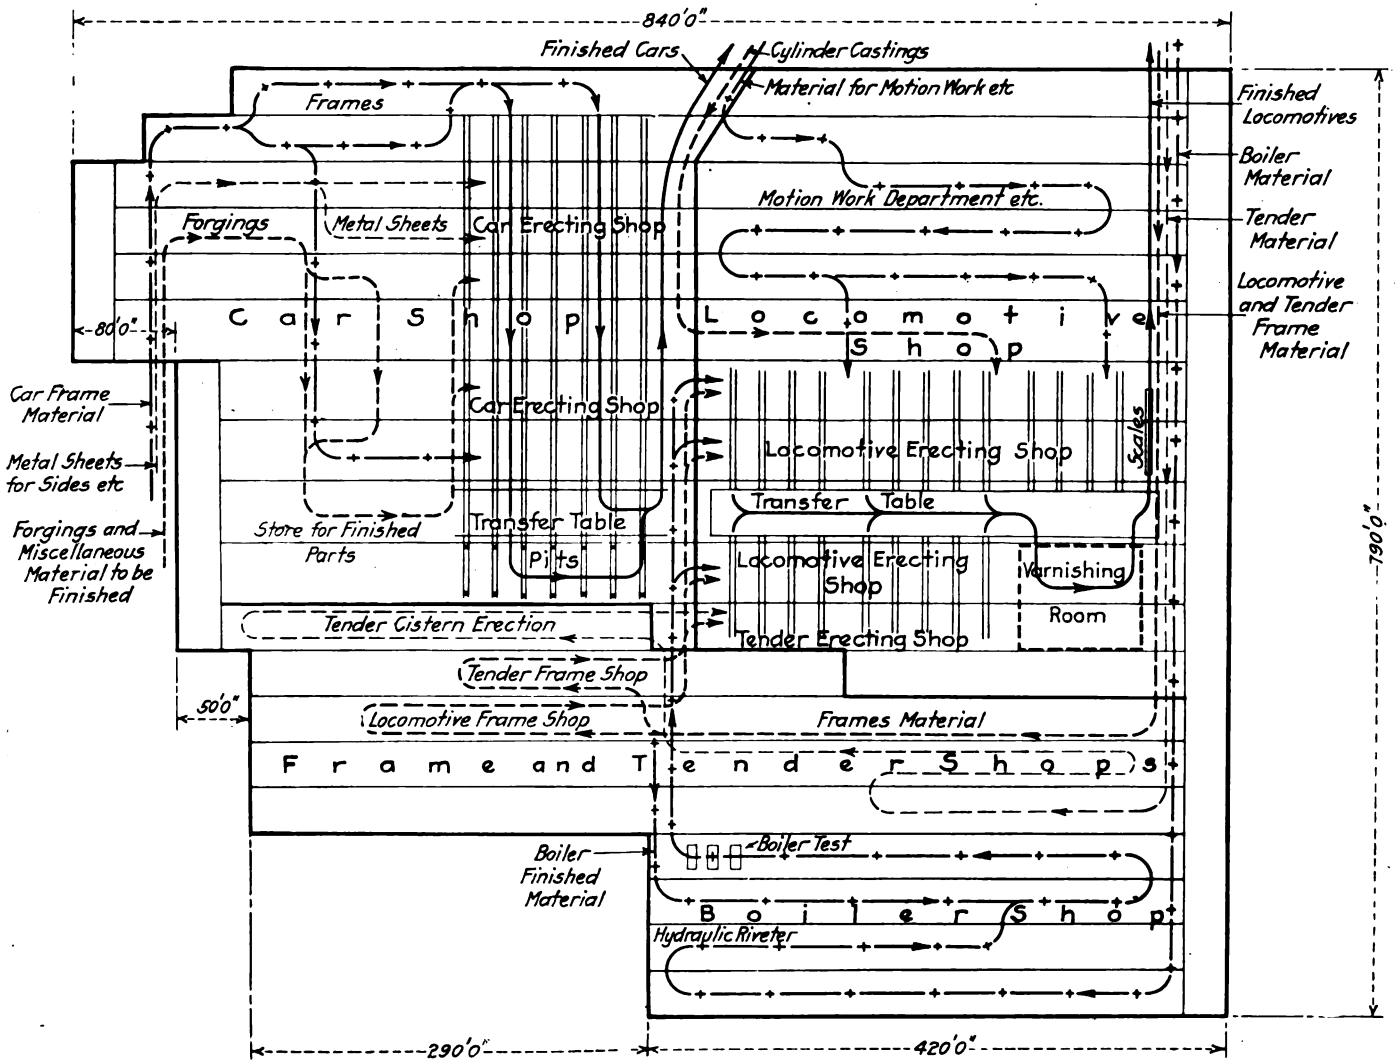

off the pits onto a transfer table and are delivered to the varnishing department where they are varnished and from there pass out over the locomotive scales to the railway by way of the southern railway siding.

The material for the car building section of the plant is delivered over the railway lead on the south or left hand side of the plant. The various finishing work is done in the bays indicated and follows on in a progressive direction to the longitudinal erecting shop and from there by means of another transfer table to the middle track and out of the shop onto the railway.

These shops are well equipped and have every convenience with the exception of a crane heavy enough to lift a finished locomotive and for this purpose electric jacks are used. The erecting pits are equipped with special gage plates not only for the standard gage but also for larger gages—for instance such as are used in Russia and Spain. Each of the manufacturing sections has its own tool department in order that the special tools required in the respective departments will be properly maintained.

through the respective bays as indicated in the diagram, the boilers and frames are delivered to the erecting shop by way of a middle standard gage track which also communicates

Soon after the armistice the work of converting this plant was done and the work on the locomotives was started in

Plan of Krupps Locomotive and Car Shop and Routing of Work

with the main line railway. Likewise the routing of tender frames and cisterns can be followed.

The cylinders and material for the driving gear are delivered to the shops by the middle track and after passing through various departments for finishing are delivered directly to the erecting shop. The finished locomotives come

March, 1919; the first locomotives and cars being turned out in December, 1919.

Export Situation in Germany

Shortly after the signing of the armistice great apprehensions were current lest Germany, in view of the low rate of

exchange which came into effect the early part of last year, should follow a policy of dumping its products on the foreign markets. To a certain extent this was done but it did not last for long on account of the lack of materials. There was a lack of sufficient labor and there was a demand for a certain amount of reconstruction within its own borders. There was a time, however, during last year when machine tools came into Holland so fast that they could not be handled. The situation grew so bad that it was not uncommon to have these exports lying in the open field uncovered and unprotected from the weather. They were sold on the ground for what they would bring.

What will be done in the future in the matter of exports depends upon the raw materials that can be obtained, and in this respect Germany is in a bad way. It suffers for the lack of coal; it must import most of its iron ore; its steel production has been greatly diminished and the labor situation has been most difficult. In addition to this the cost of labor and materials has, to the Germans, increased to an alarming extent.

In the year 1913, Germany produced about 175,000,000 tons of coal. Under the Peace Treaty it has lost about 35 per cent of its coal producing area and in addition it must deliver from 31,000,000 to 39,000,000 tons of coal to the Allies. The coal miners in Germany have the 7-hour day and the output per man has materially decreased and with it the quality of the coal.

Likewise Germany has lost 72 per cent of her ore fields and a large proportion of her pig iron and steel manufacturing facilities. The production of pig iron decreased from 19,309,000 metric tons in 1913 to 6,292,537 metric tons in 1919. Likewise the steel ingot production decreased in the ratio of 18,935,000 to 7,768,569. While the theoretical capacity of steel production under the present German boundaries is from 12,000,000 to 14,000,000 tons per year, Germany has only been obtaining a production of from 7,000,000 to 8,000,000 tons on account of the shortage of coal, iron ore

facilities for doing a vast amount of work still remains in Germany and as conditions become settled there will be a great demand for the use of these facilities. Germany is looking particularly to the Russian market. It is well known that the condition of railway equipment there is very bad and when a dependable government has been formed in Russia there will be great opportunities for big business.

It has been the policy of German industries in foreign trade to consolidate and there is at the present time an association known as the Verband Deutscher Wagonfabriken which is similar to the Railway Car Manufacturers Association in the United States, but with far greater powers

Typical Box Cars for German Railways

and more executive authority. This association has its head offices in Berlin and controls the prices of cars of all its members. Without doubt as Germany begins to find herself there will be more of these associations formed for the handling of export business.

A HOT BOX.—In connection with recent earthquakes in Mexico a darky preacher down in Texas is said to have evolved a remarkable theory, which seems to fit in very well with certain existing circumstances. He promulgates his theory of the earthquakes as follows:

"We has received anudder warnin' not to go pestica-tin' into de ways ob Providence. De earf, my breddren, revolutes on its axels, as we do now all know, and we all know dar mus' be sumefin to grease dem axels and it takes a right sma't ob grease to do it. So de good Lord done put de 'troleum inside de earf to keep de axels greased. Den byme bye 'long come all dese hyah oil companies, punchin' holes down into the bearin's and de oil all come squirten' out. Fust thing we know dar's a hot box, and de earf squeaks and jolts and rumbles and dat's de earfquake, and if dey don't quit pretty soon dere won't be no moah grease left and the earth will stick tight on its axels and won't go round no moah!"—*C. W. Savery Market Letter.*

AIRPLANE ENGINES FOR RAILWAY LOCOMOTION.—A curious experiment has been tried in Germany to lessen somewhat the consumption of coal on the railroads by equipping a car especially built for experimental purposes with airplane engines and propellers, according to an article in the *Scientific American*. The car was built for standard gage track and was equipped with two standard airplane engines and propellers. The engines are of the six-cylinder type, and most likely of 275-hp. rating. One engine is mounted above the front platform on which are two barrels of fuel and apparently two automobile radiators which have been pressed into service, and the other engine and similar equipment is over the rear platform. No attempt has been made to streamline the car further than the cutting off of its forward corners so as to give an approximate wedge-shaped front end. It is stated that with 40 people aboard, this car attained a speed of 50 miles an hour.

Cross Section of Erecting Pit In Krupps Shop Showing Arrangement for Varying Track Gauge

and the general labor conditions. As a general rule it may be stated that the cost of labor in Germany has increased from 500 to 700 per cent.

The cost of materials has risen very greatly. Basic pig iron prices have increased from about 60 marks per ton at the beginning of 1914, to 2,227 marks on March 1, 1920. Billets have increased from 100 marks to 2,290 marks. Plates have increased from 103 marks in January 1914, to 3,435 marks at the present time. Prices of ordinary steel has increased in like proportions.

These figures and the general condition of Germany today do not indicate that she will be in a position to do any very heavy export business but it must be remembered that the

A Rear View of Terminal

M. C. BUILDS ENGINE TERMINAL AT NILES, MICH.

New Division Point Established; Transfer made from Michigan City Without Serious Delay to Traffic

ON December 9 and 10, 1919, the Michigan Central placed in operation a complete new freight engine terminal at Niles, Mich., and abandoned the operation of the Michigan City, Ind., terminal except for such locomotives as are required in local work. The new engine terminal is part of a project for the transfer of the freight terminals of the Middle and Western divisions from Michigan City to Niles in order to equalize the mileage and improve

miles by the air line, while the Western division is increased to a length of 92 miles.

The terminal includes a modern 30-stall engine house of the shed-roof type, supported by four concrete posts between each pair of stalls, a 600-ton Link Belt coaling station, two cinder pit tracks over a 125-ft. concrete pit, and a six-pit locomotive repair shop. On the side of the roundhouse nearest the cinder pit, separate buildings have been erected, one to serve as an oil house and the other to house the offices of the engine dispatcher and general foreman and to provide locker room and lavatories for the engine crews. The hot water washout and filling equipment and fuel oil storage for

Interior of the Erecting Shop

operating conditions. The Middle division formerly extended from Jackson, Mich., to Michigan City, Ind., a distance of 153 miles by the main line and 141 miles by the air line, which leaves the main line at Jackson and connects with it at Niles. The Western division, from Michigan City to Chicago, was 57 miles long. With the establishment of the new freight division point at Niles, the Middle division is reduced to a length of 116 miles by the main line and 104

Relation of the Drop Pit Extension of the Roundhouse to the Back Shop

shop use are housed in separate structures adjoining the roundhouse and the powerhouse end of the repair shop building. The master mechanic's offices occupy a remodeled farmhouse fronting on what eventually will be made the main road between the division terminal and the city of Niles. Adjoining this building and also fronting on the road has been erected a two-story \$50,000 hotel, operated by the railroad company for the benefit of the engine crews.

In addition to taking care of running repair work in the roundhouse, the shops are designed to handle the classified repairs to the locomotives assigned to the Western division, thus relieving the main shop at Jackson, Mich. The entire

plant, including the terminal and shop, employs about 350 men, those in the terminal working in three shifts and those in the back shop in one shift of eight hours each. The terminal turns about 70 to 80 engines a day and keeps 8 to 12 yard engines in service, the number varying with the different shifts.

The shop output is expected to range, and has been running, from four to six heavy repairs and two light repairs per month. At the outset the shop was handicapped by a lack of its full quota of machine tools. As the new tools have been received and placed in operation, the output has improved.

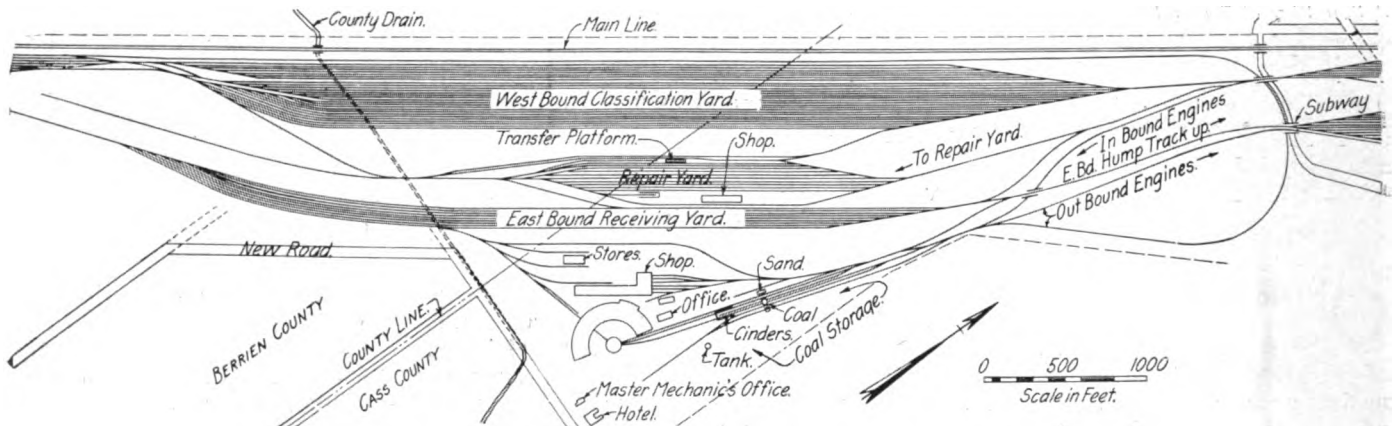

The Terminal Layout

At present only the westbound receiving and classification yards have been completed, with modifications necessary for

over the cinder pit, where cinders are dumped, wet down and shoveled by hand into cars standing on the depressed cinder track. When completed, the movement of engines in and out of the yard and through the terminal will follow the one-way plan. For outbound Western division engines this involves the use of a loop track which passes under the east and westbound humps through subways and extends alongside the entire length of the westbound classification yard to the westbound departure yard.

The Roundhouse

The 30-stall roundhouse is served by a 100-ft turntable driven by a 22-hp. heavy-duty electric tractor. It has a depth of 109 ft. 9 in., with the inside circle 95 ft. in the clear from the edge of the turntable pit. The stalls are 15 ft. wide at the doors and 25 ft. 7 in. wide at the outside wall. The

Layout Showing the Arrangement of In and Outbound Tracks

handling both east and westbound traffic. Eventually, however, the complete project will include both east and westbound receiving and classification yards, which will modify the movement of engines through the terminal somewhat from the method now employed. The engine terminal layout con-

sists of six tracks, two inbound, one outbound, one depressed cinder pit track, a coal-receiving track and an unloading track which passes over the receiving hopper of the coaling station. The two inbound tracks and the cinder pit track pass under the coaling station, the inbound tracks passing

sists of six tracks, two inbound, one outbound, one depressed cinder pit track, a coal-receiving track and an unloading track which passes over the receiving hopper of the coaling station. The two inbound tracks and the cinder pit track pass under the coaling station, the inbound tracks passing

Details of Drop Pit Movable Rail Lifting and Clamping Device

walls are of heavy, reinforced concrete 2 ft. 6 in. thick and are covered by planking, thus providing ample foundation for heavy jacking. The remainder of the enginehouse floor is covered with five inches of concrete.

Back of the seventh to the eleventh stalls, inclusive, counting from the end of the house nearest the back shop, the rear wall is offset 12 ft. 3 in. Three of the five stalls in the extension are served by drop pits. The pit for drivers is

located in the eighth stall at a distance of 70 ft. 10 in. from the inside wall of the house. This pit extends towards the seventh stall far enough to permit the location of the wheel track between the two stalls. The truck drop pit is located in stalls nine and ten, with the wheel track between them, at a distance of 79 ft. from the inside wall of the house.

The track arrangement at the drop pit section of the house is shown in one of the photographs. In the offset extension is placed a transverse track connected by two air-hoist operated turntables, with the wheel tracks from the drop pits. This track passes outside the roundhouse, through doors in the end of the offset extension, to another turntable and a track leading directly into the repair shop near the wheel lathe.

The roundhouse is provided with steam, compressed air, and cold water lines, the hot water washout and filling system lines and a fuel oil line for use in firing up. The steam blower line is carried around the house at the outside post circle with flexible pipe service connections carried down at

center of which is 46 ft. from the inside wall of the building and under the crane. These four pits are used for locomotive repairs, the wheeling and unwheeling being done on the drop pit. The outside working pit at the end of the wing is used for light and emergency repairs to locomotives when it is not necessary to drop any wheels. Owing to the location of the driving wheel lathe in the erecting shop, where crane service is available, the first pit does not extend the full width of the shop. At present the floor space occupied by this pit is used for carpenter shop and tank work.

Space is available for a future extension of the erecting shop at the end of the wing, as well as for the installation of a screwjack locomotive hoist.

The drop pits, both in the erecting shop and roundhouse, are designed for operation without the necessity of men entering the pits either for jacking, traversing or removing the rails. The jack is traversed along the pit by means of an air cylinder located alongside the jack track. The removable rail sections in the engine pit tracks are carried on simple

Interior of the Roundhouse, Showing the Extension at Drop Pits and the Wheel Track Arrangement

each post. All other pipe lines are placed at the second post circle from the inside wall, the service connections being carried down at alternate posts, each set thus serving two stalls. The hot water, filling, washout and blowoff lines are carried outside or back of the posts, with the cold water, compressed air and fuel oil lines opposite. Each service outlet on the fuel oil line is fitted with a permanent hose and burner connection.

Erecting and Machine Shops

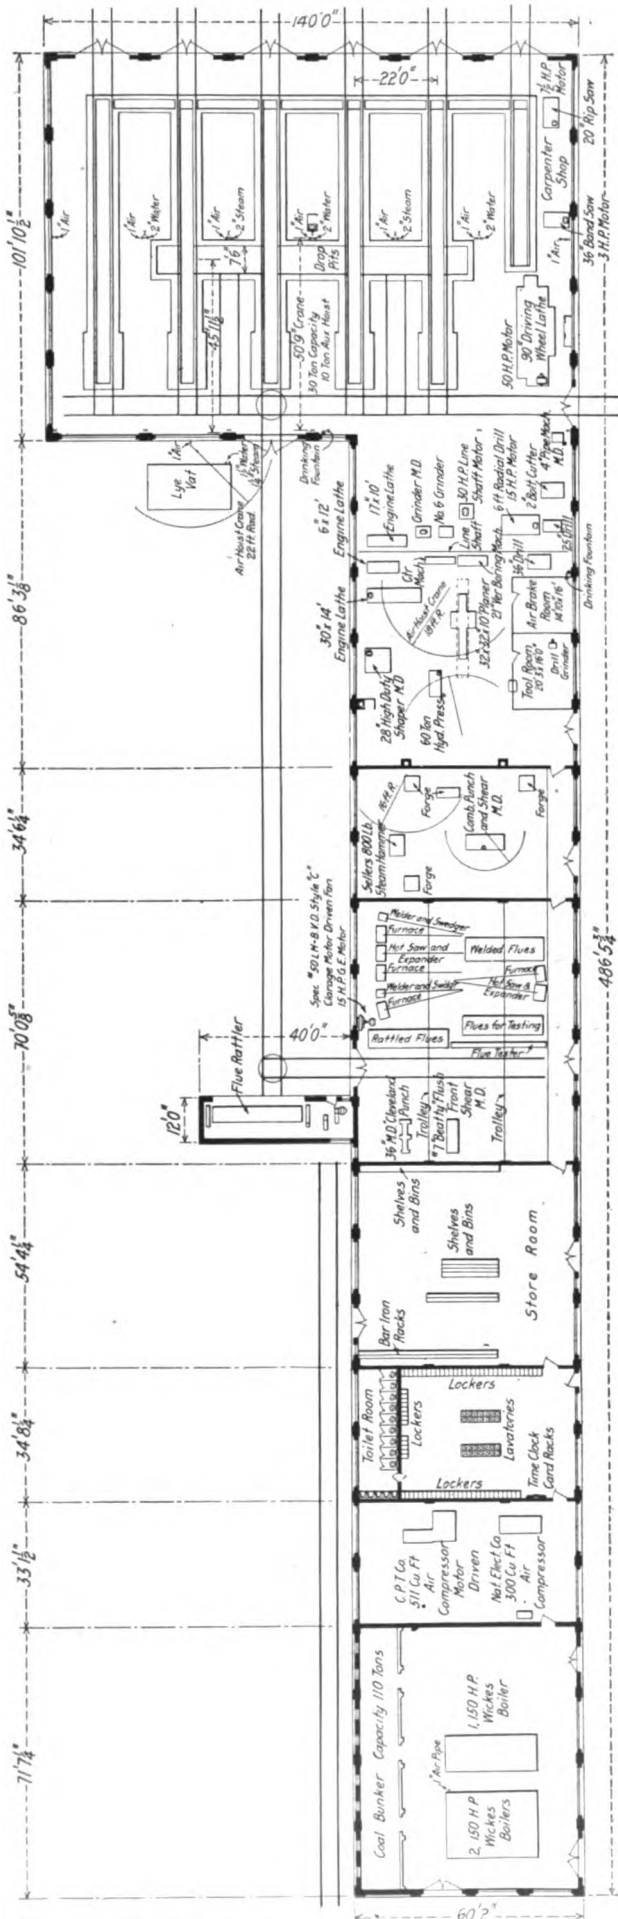

The repair shops, storehouse and power plant are housed in a single structure. This building is L-shaped, 486 ft. long and 60 ft. wide, with a 140-ft. wing, 102 ft. deep at one end. The erecting shop, which occupies the wing, is divided into two longitudinal bays 46 ft. and 53 ft. wide, with the wider bay adjoining the machine shop. A 30-ton Northern crane, with a 10-ton auxiliary hoist, travels throughout the length of this bay. There are six transverse pits in the erecting shop, spaced 22 ft. between centers. The four middle working pits are served by a continuous drop pit, the

elevating trucks, on which they are readily moved along the drop pit.

The movable rails are of 80-lb. section and are mounted on 12-in. 40-lb. I-beams. At each end two five-inch flanged wheels are attached to opposite sides of the I-beams, with swinging arms and a toggle link mechanism which permits the wheels to be lowered sufficiently to raise the I-beam free from its supports. The wheels rest on rails laid along the sides of the jack pit.

In dropping a pair of wheels, after they have been raised clear of the movable rails, the five-inch wheels are lowered by means of a lever which may be reached without entering the pit and the rail is rolled ahead of the jack to be placed in line with the wheel track after the wheels have been raised. Similarly, the other movable rail is moved up behind the jack, lowered in place, the wheels dropped on the rails and rolled off the pit. The operation of the jack and the jack traversing cylinder are controlled by valves located at the columns between the engine pits.

The machine shop occupies 86 ft. of the longitudinal por-

Plan of the Main Shop Building including the Store and Power Plant

tion of the building adjoining the erecting shop. In addition to the old machine tools transferred from Michigan City, a number of new machines are being installed as fast as deliveries can be secured. These include a 90-in. wheel lathe, a vertical turret lathe, a 28-in. high-duty shaper and an 18-in. engine lathe. The majority of the older machines are group driven from a line shaft by a 30-hp. motor. The arrangement of the machine tools, which have already been placed in operation, is shown in the plan drawing of the shop.

Smith and Flue Shops

Adjoining the machine shop is the blacksmith shop, the two being separated by an 8-in. brick wall. The blacksmith shop occupies 34 ft. 6 in. of the building for its full width. It contains three hand forges, an open fire for large bar stock or other similar material, one 800-lb. steam hammer and a motor-driven combination punch and shear. The hammer, one of the hand forges and the open fire are under the swing of a 16-ft. jib crane and a smaller jib crane swings over the punch and shear.

The flue shop, which adjoins the blacksmith shop, is 70 ft. long and is closed at either end by 8-in. brick walls. Near the farther end of this shop a dry flue rattler is housed in a small structure built out from the side of the building adjoining the erecting shop wing. Counting from the machine shop end, the track over the third working pit in the erecting shop passes through the wing and is continued to the flue rattler. Provision is thus made for the movement of tubes from the erecting shop to the rattler, and thence they are moved directly into the flue shop on a transverse track connected with the longitudinal track by a turntable.

From the floor plan it will be seen that the path of the tubes through the shop is in the form of a loop starting from and ending at the transverse track, where the tubes are loaded on trucks for the return movement to the erecting shop.

The equipment of this shop consists of a welder and swager for superheater flues, a Ryerson combined hot saw and air-operated swaging and safe-ending machine for 2-in. tubes, a hot saw and expander for the front tube sheet ends of 2-in. tubes and a hydraulic tester. The swaging and welding machines are served by Economy combustion chamber furnaces burning fuel oil.

The Power Plant

The remainder of the building is occupied respectively by a 54-ft. store room, lavatory, locker and toilet rooms 35 ft. long, and the power plant. The latter is divided into two sections, the first of which occupies 33 ft. of the building and contains two air-compressors, one a new belt-connected, motor-driven compressor furnished by the Chicago Pneumatic Tool Company, of 511 cu. ft. capacity, the other a direct-connected, motor-driven compressor of 300 cu. ft. capacity, which was moved from the Michigan City shop.

The boiler room is 71 ft. 7 in. long, and at the present time contains three 150-hp. Wickes boilers, with room for the addition of two more units of the same size. An enclosed coal bunker of 110 tons' capacity is built in along one side of the boiler room. Along this side of the building is located a track which serves both the store room and the coal bunker.

All power for machine-tool drives, welding and lighting is three-phase, alternating current, furnished by the Indiana-Michigan Power Company of South Bend, Ind., at 4,000 volts, with transformers installed at the shops. The power and welding circuits are stepped down to 440 volts, while the lighting circuits are taken from a three-wire, 220-volt transformer, with the circuits arranged for 110-volt lamps.

Lighting

Both the shops and the roundhouse are lighted by 200-watt lamps in Maxilight reflectors. In the shops the lamps are suspended from the under side of the roof trusses. In the

roundhouse the wiring conduits and fixtures are carried on messenger cables suspended along each radial row of posts about 14 ft. above the floor. Each row carries two lights, alternating respectively between the middle of the first and third bays and the middle of the second and fourth bays. Drop cords for use with extension cord lamps are located near the second and third posts in each row.

The roundhouse eventually will be wired with a 440-volt circuit to permit the use of electric welding apparatus.

The Transfer from Michigan City

The placing in operation of the new terminal involved problems not usually encountered when moving into new shops. Practically a complete transfer of shop tools and equipment, material and working forces from Michigan City to Niles, a distance of 37 miles, was required. The distance made it necessary to arrange the transfer so that practically full running repair work could be continued at Michigan City to within a few hours of the time that all work was to be handled at Niles.

About a week before the proposed change all of the heavy machine tools, including the old wheel lathe, were moved to Niles, leaving only such of the smaller tools as were absolutely essential to maintaining running repairs at Michigan City. On December 8 and 9 a gang of machinists was sent to Niles to connect up and place the tools in operation.

From noon of December 9 all westbound Middle division trains were stopped at Niles and eastbound Western division trains were run through Michigan City to Niles. Enough mechanics were sent to Niles on the morning of the ninth to take care of the gradually increasing business from noon of December 9 to the morning of December 10.

On the evening of December 9 six cars of supplies and one car fitted up as a temporary tool room were despatched from Michigan City, arriving at Niles in time for the 6 o'clock morning business. By December 11 the new terminal was practically in full operation and only such power remained at Michigan City as had not yet been despatched following its arrival prior to noon of December 9. As rapidly as possible the supplies and tools were removed from the cars to their permanent quarters in the shop building. Most of the men still reside at Michigan City, and special shop trains are operated between Niles and Michigan City for their benefit.

The change was made with a minimum of light-engine mileage and no serious delays to traffic resulted, although some time was required to get the terminal as a whole to working smoothly. As has been stated, only the westbound receiving and classification yards have at present been completed with modifications necessary for handling both east and westbound traffic. The principal handicap in this respect was the fact that the eastbound yards were required to handle both east and westbound traffic, rather than any condition in the engine terminal itself.

FREDERICK J. HARRISON

Frederick J. Harrison, superintendent of motive power of the Buffalo, Rochester & Pittsburgh since 1910, died at Du Bois, Pa., on April 16, following an illness of several months resulting from pneumonia. As superintendent of motive power of the Buffalo, Rochester & Pittsburgh, Mr. Harrison had full supervision over the executive and technical duties of the motive power department, which although not as large as that on many railroads was generally regarded as a model with respect to management and perfection of mechanical detail.

Mr. Harrison was born in Rochester, N. Y., on February 22, 1864, the son of Joseph Harrison, who was one of the old engineers on the New York Central. He attended school until he was 14 years of age and then started to learn the machinist trade, which vocation he followed for 11 years, being connected during this time with the Gleason Machine

Works and the Graves Elevator Works. He then became a fireman on the New York Central, remaining in that service for about three years, sending in his resignation just one day before he was to be promoted to engineer. He resumed work as a machinist in October, 1888, in the shops of the Buffalo, Rochester & Pittsburgh at Rochester. In 1890 he was placed in charge of the shops as machine foreman and in 1894 was made general foreman in charge of the locomotive and car works at that point, which position he held for six years.

In 1901 Mr. Harrison accepted a position as general foreman at the Du Bois Iron Works, but shortly after moving to Du Bois he re-entered the service of the B. R. & P. as general foreman of the shops then in course of construction at Du Bois. He supervised the installation of machinery, thus starting the new work at this point. Mr. Harrison was promoted to the position of master mechanic in 1904, having charge of

the locomotive and car works not alone at Du Bois, but all points between East Salamanca and Pittsburgh. In 1910 he became superintendent of motive power.

Mr. Harrison was practically and thoroughly educated in his line of work. His judgment was held in high esteem by officials of the railroad with which he was connected, and his opinion and advice were sought at all times. Mr. Harrison had the opportunity to become more prominently identified with the activities of the community in which he was located than many railroad officials who are situated in larger centers, and it may be said that he contributed much toward establishing a friendly understanding between the public and the railroad that he represented. He was a prominent Rotarian and was affiliated with other local and Masonic organizations. Although Mr. Harrison held a position that frequently brought him in opposition to employees of the railroad, he always retained their confidence and a reputation for fair and square dealing that is recognized today as so important a factor on all railroads.

F. J. Harrison

Output of Automatic Machines on the Inspection Bench

AUTOMATIC MACHINES AN AID TO ECONOMY

Work for Which Various Types Are Adapted; Minimum Quantity Economically Produced on Automatics

BY GEORGE W. ARMSTRONG

AUTOMATIC machine tool installations offer a possibility for reducing maintenance of equipment expense which has been largely overlooked. The urge has not been as imperative in the past as at present; due to the higher labor rates and individual decreased productive efficiency. Human nature is so constituted that it normally follows the line of least resistance. This results often in a tendency to stick to the old way, the means that are familiar, rather than to investigate and develop the latent possibilities of the unknown and untried. This may account in part at least for the meagre adaptation of automatic machine tools.

Lack of initiative should not become an insurmountable barrier to the realization of the sure economies, which can

and turning lathes and 3 automatic chucking lathes. The other has 34 single spindle automatic screw machines, 14 multiple spindle screw machines, 15 automatic chucking and turning lathes and 4 automatic chucking lathes. And this latter road is figuring on additional machines.

The Field for Automatics

Automatic machines are desirable in that more than one machine can be cared for by one operator because of the automatically controlled tool movements, spindle speed and feed changes. They are further, especially advantageous, due to the feature of mechanical output pacing. Manual labor in machine tool operation is largely transferred by automatic machines from the man to the machine. Productive capacity is controlled by fixed work cycles and the output expected is therefore definitely fixed, except for the contingencies of tool grinding, resetting tools and minor delays. This desired output is being used by at least two roads as a mark to shoot at, and the best of co-operation secured in realizing and often bettering this mark. Mechanical control of production as given by automatic machine operation has been a satisfactory means of securing uniform output and leveling the peak.

Automatic machine tool operation does not lend itself to promiscuous shop installation; to secure full benefits centralized installations should be made. Attaining full productive capacity requires that they be grouped at one point, where tooling equipment can be made and maintained, and where an organization can be built up to care for them. The automatic machine as now developed with standard tooling equipments is not a difficult machine to operate; standard cams have been developed too, which will take care of all usual ranges of work and these are very easily removed and reapplied.* Grouping of machines at one point, results in reduction of the idle investment in these auxiliary parts, as well as securing an experienced trained force to successfully devise the best uses of standard tools, and develop any special tools which may at times be required.

The natural result of centralized installation of automatic machines is the centralized production of parts and standardization as far as possible of suitable parts for such production. This, however, should not be a deterrent but a decidedly beneficial by-product. Centralized production of

A Multiple Spindle Automatic

be effected through the acquisition of such valuable shop adjuncts. Their possibilities are not untried and unknown. Automatic screw machines have been in successful operation in railroad shops since 1900 and automatic chucking and turning lathes since 1905. Automatic screw machines are now being operated on eight or ten roads with profit, while automatic chucking and turning lathes are similarly successfully operated on three roads.

The degree of usefulness of automatics is further well illustrated by the scope of two large railroad installations. One road has 12 single spindle automatic screw machines, 4 multiple spindle screw machines, 16 automatic chucking

*For a discussion of the operation of automatic machines, see article "Automatics in Railroad Shops," published in the *Railway Mechanical Engineer* issue for June, 1919, page 303.

largely used repair parts exerts a greater improvement in roundhouse maintenance than in shop operation and individual part cost economy. The effect in roundhouse operation is largely an intangible one from a dollars and cents standpoint, but an important one. Having in stock a finished or semi-finished part may often mean the difference of hours in returning an engine to service, and may in many instances prevent the loss of an engine on its regular run.

Types of Automatic Machines

Many types of automatic machines are available, but the particular type best suited depends upon the nature of the work. The following is a list of representative automatic machines of the more common types.

- Automatic Lathes..... { Fay automatic.
Reed-Prentice automatic.
Le-Blond Multi-cut.
- Automatic Chucking and Turning Lathes { Potter & Johnston.
Guisholt.
- Automatic Chucking Machines.... { New Britain.
Bullard Multi-av-matics.
- Automatic Screw Machines, Single Spindle { Gridley.
Brown & Sharpe.
Hartford.
Cleveland.
- Automatic Screw Machines Multiple Spindle { Gridley.
National Acme.
Radical.
New Britain.
Cincinnati.
Cone.
- Automatic Milling Machines..... { Cincinnati.
Potter & Johnston.
Pratt & Whitney.

Best Types for Handling Various Kinds of Work

Automatic Lathes.—The automatic lathe is adapted for straight multi-diametered work with limited facing requirements. Front, back and intermediate crank pins are within

Locomotive Parts Produced on Automatic Screw Machines

its scope, but require the use of an auxiliary machine for threading, preferably a thread milling machine. Cross-head and knuckle pins could be similarly finished, and also motion work pins where the quantities required are too small to justify the use of automatic screw machines, or where a large head makes turning from a forging more economical than from bar stock. Flanges, crank pin collars, and similar work requiring only turning and facing can be admirably handled on this type of machine by using mandrels.

Automatic Chucking Machine.—The automatic chucking machine is best adapted to boring, reaming and facing opera-

tions on small castings or forgings which can readily be held in chuck jaws. Its high productive capacity makes it suitable only for large quantity runs. This type of machine has five or more chucks with four or more tool working stations. The chucks are indexed so as to present the work to the respective tool stations in sequence. Work is therefore finished in the time required to perform the longest single operation, plus the time required to index the head. Removing and chucking pieces is done at the same time that machining is being done.

Multiple Spindle Screw Machine.—The multiple spindle automatic screw machine should be used where large production runs are available as staybolt sleeves, link bushings, set screws, etc. The use of the multiple spindle machine, however, is not advisable for initial installations, general use and large diametral capacity, for which purposes

A Typical Tool Set Upon a Multiple Spindle Screw Machine

the single spindle automatic screw machine is better suited. Where the quantities required are large the multiple spindle machine is desirable as it combines four or more machines in one, and the work is produced in the time of the longest single operation plus the time to index the spindle head. Tools are operated on each bar in succession, cutting off the finished piece in the fourth position, ready to feed the bar forward as the head indexes. Production time can be reduced by dividing the longest operation between two spindles wherever possible, for example, a long turning or drilling operation. Threading can be done on an automatic screw machine, but it will usually be found that greater production, due to higher cutting speed and feed, can be secured if threading is done independently, preferably on a bolt threading machine. Where a set-up man is employed, a substantial reduction can be effected by using a machinist helper to thread parts and the set-up man to adjust the dies.

Automatic Milling Machine.—The automatic milling machine has been very little utilized in railroad shops except for milling square and hexagon bosses on caps and similar pieces. Aside from the Potter & Johnston machine, those available are rather restricted in scope which may partly account for this fact. Then, too, the latest type of plain, knee type milling machines are equipped with trip dogs for table movement which make them semi-automatic in operation. However, there is considerable milling work in large quantities as rod keys, piston keys, shoes, etc., which could be profitably handled on automatic milling machines and deserves consideration.

Automatic Chucking Machine.—The automatic chucking machine is well adapted to finishing castings and forgings.

Tool set-up is virtually that of good turret lathe practice, using multiple tooling set-ups, for simultaneous turning, boring, drilling or reaming with turret face and facing with the cross-slide. The turret travel and indexing, cross-slide movements, spindle speed and turret and cross-slide feeds, as well as the co-ordinated operation of turret and cross-slide are controlled by trip dogs and cams on the cam shaft in the base of the machine. The articles to be machined are usually held by means of a regular convertible two-jaw to three-jaw universal lathe chuck, fitted in most cases with false jaws. Wherever it is possible to true the false jaws in place, they are left soft and frequently trued up to maintain accuracy, especially where holding a turned surface for a second operation.

All operations of this type of machine are automatically performed after the piece is chucked and the starting lever thrown off. At the completion of the cycle, the machine is automatically tripped and stopped, thus preventing a repetition of the cycle and possible spoiling of work should the operator be occupied elsewhere. This feature can also be made use of in tapping or threading with a collapsing tool. To insure the operator's attention during this operation, the threading tool can be placed on the first face, so that the automatic trip feature stops the machine prior to this operation. It then requires the operator to start the machine for

A Battery of Automatic Chucking Machines

threading or tapping and to also stop it again to remove the piece and chuck a new one.

This type of machine is now being used for a wide range of parts, some of which are given below.

- | | |
|------------------------------|-----------------------------|
| Bell ringer cylinders. | Injector flanges. |
| Bell ringer pistons. | Crank pin collars. |
| Air pump piston heads. | Knuckle pins. |
| Tank hose nuts. | Air valve cages. |
| Injector pipe nuts. | Eccentric rod bushings. |
| Crosshead pin nuts. | Piston valve bull rings. |
| Knuckle pin nuts. | Piston valve packing rings. |
| Air pump packing rings. | Boiler check bodies. |
| Oil cup covers. | Grease cup covers. |
| Packing sliding plate rings. | Knuckle pin bushings. |

Single Spindle Screw Machines.—The single spindle automatic screw machine has perhaps the largest field in railroad shops. The set-up required is less complicated than that of the multiple spindle automatic screw machine, and the range in the diameter of bar greater. This greater simplicity in tooling and camming makes it possible to utilize it for much work in quantities too small for economical multiple spindle production and which would otherwise require the use of a turret lathe. Turret lathes have a very wide field of usefulness in railroad as well as industrial shops which has by no means been fully developed. However, the turret lathe requiring individual attention and operation should not be used, where runs of articles are required in quantities adapted to automatic machine production and consequent multiple machine operation.

Automatic screw machines, single and multiple spindle, are used in railroad shops for finishing the following parts:

- | | |
|-------------------------|--------------------------|
| Crosshead shoe bolts. | Spring rigging bushings. |
| Spring bolts. | Spring rigging pins. |
| Brake bolts. | Lift shaft bolts. |
| Reach rod bolts. | Rod dowels. |
| Trailer box bolts. | Eccentric set screws. |
| Patch bolts. | Brake rollers. |
| Eccentric rod pins. | Studs. |
| Valve rod pins. | Reversing valve plates. |
| Motion work bushings. | Oil cups. |
| Link pins. | Main rod key washers. |
| Throttle lever bolts. | Nuts of various kinds. |
| Lubricator connections. | Packing glands. |
| Staybolt sleeves. | Valve stems. |
| Taper pins. | Set screws. |
| Cap screws. | |

Operation of Automatics

Two to four automatic screw machines are being handled easily by one operator and generally two automatic chucking and turning machines. The automatic chucking lathe is a multiple chuck machine and requires one man per machine. Many industrial installations have been made where the operator takes care of an automatic chucking and turning machine and one or two single or multiple spindle automatic screw machines, which practice might be followed in initiating railroad installations.

Complete, detailed records should be kept of the camming and tool set-up for each job, so as to prevent the necessity of the operator remembering the set-up or as is more often the case, working it out again, which is necessarily a waste of time. This record will also serve to preserve the best set-up features and insure maximum production at all times. Record sheets are generally furnished by the machine manufacturer on request.

Maintenance of Automatics

The operating statistics of one large railroad installation may be of interest as showing what has been accomplished with automatic machines and also to show that they are not difficult machines to maintain in repair. With the exception of abnormal allowance for one group of two machines, the figures show very good performance, and demonstrate that automatic machines are consistent producers with little delay for repairs.

	Average	132.2	224.9	145.1	2,649.3

Minimum Economical Run

The question often uppermost in the mind of the man considering automatic machine operation, or contemplating new work on his existing installations, is, "What is the minimum quantity I can afford to run?" An accurate answer must necessarily require accurate data which would not be available. However, an approximate solution which will fulfill the object desired can be secured from previous similar performances or conservative estimated time. The same method can also be employed to determine accurately the

quantity after actual operating figures have been developed.

The minimum economical production will necessarily be such a quantity that the automatic machine cost will be equal to the cost on the turret lathe. Material will not differ in either case, where good practice prevails, so that this item can properly be disregarded. This will be true except in the limited cases where forgings might be used in turret lathe practice, whereas the automatic screw machine would produce from bar stock. Forging cost will often serve as ample offset to the extra material cost, or else the use of the proper automatic machine will again duplicate turret lathe procedure in finishing the forgings. Direct labor cost and overhead expense are therefore the determining factors governing the minimum economical production.

- Let s = set-up time in hours on the automatic
- s_1 = set-up time in hours on the turret lathe
- t = production time in hours per piece on the automatic
- t_1 = production time in hours per piece on the turret lathe
- n = number of pieces to be finished
- q = number of automatic machines operated per operator
- r = hourly rate of the automatic operator
- r_1 = hourly rate of the turret lathe operator
- R = hourly rate of the automatic set-up man
- O = rate in per cent of automatic overhead expense
- O_1 = rate in per cent of turret lathe overhead expense

The cost on the automatic machine will be

$$s(r + R) + \frac{ntr}{q} + \frac{O}{100} \left[s(r + R) + \frac{ntr}{q} \right]$$

The assumption has been made that while setting up a machine the other automatic machines in the individual battery will be idle. While not strictly true for automatic screw machines, until material being worked on is cut up, it will be realized that this assumption is an error on the side of safety, as the benefit is given for any production resulting during the time of setting up.

Also the cost on the turret lathe will be

$$s_1 r_1 + n t_1 r_1 + \frac{O_1}{100} \left[s_1 r_1 + n t_1 r_1 \right]$$

Equating and solving we have

$$n = \frac{\left[\left(1 + \frac{O}{100}\right) s(r + R) \right] - \left(1 + \frac{O_1}{100}\right) s_1 r_1}{\left(1 + \frac{O_1}{100}\right) t_1 r_1 - \left(1 + \frac{O}{100}\right) \frac{tr}{q}}$$

Solving this equation will give the minimum economical production run for any particular job to compete with turret lathe operation. Illustrative of its practical application we will assume a typical case, and solve for the economical quantity.

- Let s = automatic set-up time be 4 hrs.
- s_1 = turret lathe set-up time be .5 hrs.
- t = automatic production time be .1 hr.
- t_1 = turret lathe production time be .25 hr.
- r = automatic operators rate .72 per hour
- r_1 = turret lathe operators rate .76 per hour
- R = Set-up man's rate .84 per hour
- d = automatics per operator, 2
- O = overhead on automatics 175 per cent
- O_1 = overhead on turret lathe 60 per cent

Then

$$n = \frac{\left[\left(1 + \frac{175}{100}\right) 4 (.75 + .84) \right] - \left(1 + \frac{60}{100}\right) .5 \times .76}{\left(1 + \frac{60}{100}\right) .25 \times .76 - \left(1 + \frac{175}{100}\right) \frac{.1 \times .72}{2}}$$

Solving n or minimum production = 44.3 pieces.

Automatic machines have been a profitable investment for the railroads now using them. The statement was recently made that two months' production on one multiple spindle automatic screw machine saved enough to pay for the machine. This was an exceptional result, but the possibilities for economy are large.

Automatic machines will produce and they will produce uniformly. The care and attention required to effectively maintain an automatic machine is no more than that which should be accorded any other machine tool. The unfavorable contrast where it does exist is due to an inferior maintenance of general purpose machine tools, and that an engine lathe

"shot to pieces" can be made to produce where an automatic machine will not effectively.

Labor rates are high and will continue high, individual productivity is low and may be improved in time; but auto-

RANGES IN STEAM CONSUMPTION BY PRIME MOVERS

Fuel consumption is the direct result of water evaporated and evaporation depends on the steam demands of the engine. The following table shows steam consumption under average plant conditions for different types of engines using saturated

Type Engine	Steam consumption, lb. per hp. hr.		
	Saturated steam	100 Deg. superheat.	200 Deg. superheat.
Simple non-condensing	29-45	20-38	18-35
Simple non-condensing automatic	26-40	18-34	16-30
Simple non-condensing Corliss	26-35	18-30	15-22
Compound non-condensing	19-28	15-25	9-17
Compound condensing	12-22	10-20	9-17
Simple duplex steam pumps	130-200	80-160	21-48
Turbines non-condensing (kw. hr.)	28-60	24-54	21-48
Turbines condensing (kw. hr.)	12-42	10-38	9-34

steam compared with those using superheated steam at 100 deg. and at 200 deg. superheat.

Depending on the efficiency of the engine itself, it will be seen that superheating shows substantial economies in steam consumption. It should be noted, also, that the percentage of savings varies from 9 to 33 per cent for 100 deg. superheat to from 19 to 38 per cent for 200 deg. superheat.—*Power Plant Engineering.*

AIR BRAKE ASSOCIATION HOLDS LIVE CONVENTION

Important Problems Dealt with from Standpoint of Effect on Revenue and Operating Efficiency

SUBJECTS having an important bearing on railroad operating conditions were discussed at the twenty-seventh annual convention of the Air Brake Association, which opened on May 4, at the Hotel Sherman, Chicago.

Following the usual opening exercises, Frank McManamy, manager department of equipment, Division of Liquidation of Claims, United States Railroad Administration, delivered an informal address, which was followed by the address of T. F. Lyons, president of the association.

Mr. McManamy's Address

In his talk Mr. McManamy offered two suggestions for the consideration of the association. He first drew attention to the comparatively small number of men who are charged with the responsibility of supervising the main-

of control by the members of the association and other railroad men.

Address of the President

In his address, President Lyons dealt particularly with the advantages of attendance at the convention and the responsibility of the members to participate in the activities of the association. Foremost of these is the responsibility of taking such an interest in the discussion as will insure that each subject is thoroughly covered, the time and labor expended in the preparation of papers and committee reports for presentation meriting the most careful attention by the members. Among the benefits which the members receive from convention attendance, Mr. Lyons dwelt on the opportunity to talk shop with other air brake men outside the convention hall, from which talks are received many valu-

Second Vice-President

tenance and operation of air brake equipment. This was brought out forcibly by comparison with the equipment under the supervision of the road foreman of engines. Each road foreman supervises the operation of the locomotives on one division or less, these locomotives always remaining on the division and running into one or the other of the terminals at least once every 24 hours where they are available for necessary repairs. Usually one air brake supervisor, alone or with comparatively few assistants, must supervise the air brake equipment in operation on an entire system, much of which, in the case of freight cars he may never see but once during its life.

Mr. McManamy suggested that air brake departments need reorganization to provide more supervisors directly responsible for air brake conditions, to provide adequate equipment for making repairs, not at one terminal alone, but at every terminal on the road and he pointed out that to secure these things the support of the management must be secured. As one means of securing this needed support, he recommended that the Air Brake Association affiliate with the American Railroad Association, as such affiliation would bring the recommendations of the air brake men of the country in a position to receive the backing of an authoritative body.

In closing Mr. McManamy paid a high tribute to the support given the Railroad Administration during its period

able suggestions directly applicable to the solution of his own problems by each member.

BETTER MAINTENANCE OF AIR COMPRESSORS*

By Mark Purcell
General Air Brake Inspector, Northern Pacific

When direct inquiry is made, the usual impression is that compressors are giving good service. At the same time service records may show a large amount of wheel sliding and breaking in two of trains that, at first, does not appear to have any relation to the manner in which the compressors are operating, for which the compressor is largely responsible.

If a compressor runs slow, or for any reason raises pressure slowly, there may not be enough accumulated after a brake application to make a proper release, with the result that a part of the brakes only are released and wheels are slid or drawbars pulled out. Still the compressor has not actually refused to work.

Most of the low efficiency and some of the failures are due to lack of repairs, or the quality of the repairs made being often only slightly below the standard required. In

*Submitted by the North-West Air Brake Club.

some cases it is an error in a single feature, but more often a combination, such as a number of leaks, any of which may be too slight to cause trouble, yet when combined are serious. The above applies more particularly to compressors having steam and air cylinders compounded, on account of the balancing effect that may be caused by leakage.

It is not uncommon to find a compound compressor that is chronically inefficient, and be advised that one part after another has been repaired or replaced, until all or nearly all of the working parts have been gone over, and yet the operation is not improved.

In one case an 8½ in. cross compound compressor developed pounding, would not supply sufficient air, and the engine had to be taken off an important train. Examination showed that the rings in both the high and low pressure air pistons were 3-16 in. to 5-16 in. open at the ends and lacked about .0012 in. of filling the ring grooves. New rings that would fit the cylinders, .0012 in. smaller than the grooves, were applied to both the air pistons, and the compressor gave good service for four months, and probably longer.

Another 8½ in. cross compound compressor pounded to some extent and ran so slow with 190 lb. steam pressure that

pressor came into use, but general observation would indicate that these appear seldom to be considered in connection with compressor maintenance. The general standard of service of these compressors is thus considerably below what may reasonably be obtained at slightly increased cost, by simply following standards such as those outlined in the recommended practice by the Air Brake Association.

The number of engine failures chargeable to the air compressor alone, indicates the need for improved compressor maintenance, and this is emphasized by the other troubles that can readily be traced directly to a lowered compressor efficiency.

Discussion

The paper drew out a lively discussion which, however, dealt more with the various causes of failure, particularly of the cross compound pump, than the details of maintenance. One of the most frequently mentioned causes of failure was improper lubrication, there being set forth a diversity of opinions and methods for oiling the air cylinders of the cross compound compressors, but a general agreement that a satisfactory system of lubricating these cylinders has yet to be developed. One of the measures to be taken to

G. H. Wood (A., T. & S. F.)
Third Vice-President

F. M. Nellis (Westinghouse Air
Brake Co.) Secretary

Otto Best (Nathan Mfg. Co.)
Treasurer

it would not keep up 90 lb. standard brake pipe pressure on a regular passenger train of 10 cars, against normal leakage. Examination showed:

- (a)—Main steam and air cylinders slightly worn.
- (b)—Steam cylinder head parts in good condition.
- (c)—Main steam and air pistons about 1-32 in. smaller in diameter than their cylinders.
- (d)—Packing rings in steam and air cylinders came together at the ends in the smallest part of the cylinders and were a little less than 3-32 in. open in the largest parts of the cylinders.
- (e)—Rings lacked .005 in. to .008 in. of filling the grooves in the high pressure steam cylinder.
- (f)—Rings in the low pressure steam cylinder lacked .0012 in. to .0015 in. of filling the grooves.
- (g)—Rings in the high pressure air cylinder lacked .0015 in. to .0018 in. of filling the grooves.
- (h)—Rings in the low pressure air cylinder lacked .0012 in. to .0015 in. of filling the grooves.
- (i)—The upper final discharge valve had 3-16 in. lift, one upper intermediate valve had 7-32 in. lift and the other air valves had only slightly more than standard lift.

New pistons that would fit the cylinders closely at the smallest part, and in which the rings fitted the grooves with just enough clearance to expand by their own tension when compressed into the grooves, were applied and no other repairs made. The compressor was given a severe running test in which its capacity and speed were fully up to the standard.

Recommended standards to cover repairing and adjustment of the different parts of compressors have been published extensively and discussed ever since the cross compound com-

avoid air pump failures and excessive maintenance is to give close attention to brake pipe leakage and in doing this not to overlook the brake cylinder.

The suitability of the orifice condemning test as a means of determining whether a pump is in condition for every class of service was questioned by several members, and was the subject of considerable discussion. The point was made that a pump which may just pass the condemning test may not be suitable for service on long, heavy trains in heavy grade territory. It was brought out in the discussion that the Interstate Commerce Commission condemning tests allow only about 10 per cent depreciation below the rated capacity of cross compound pumps, while the percentage is higher for other types and it was suggested that the degree of efficiency essential in any particular class of service should first be established and the test for that class of service modified to maintain that efficiency.

The members quite generally agreed with the author of this paper as to the desirability of tightening up generally on air compressor maintenance, one of the reasons that was particularly stressed being the damage done in service by failure of the brakes properly to release in cycling, this being frequently caused by the inability of a poorly maintained pump to raise the main reservoir pressure within the time allowed by the cycle, even though it may pass the condemning test.

TERMINAL TESTS OF AIR BRAKES

By W. P. Borland

Chief Bureau of Safety, Interstate Commerce Commission

There is no disposition on the part of the Interstate Commerce Commission at the present time to take extreme measures in its administration of the power brake provisions of the safety appliance law; but the time has arrived when better observance of the requirements of law by those who are responsible for the condition of air brake equipment may well be insisted upon.

The percentage of non-air cars now in service is so small as to be negligible. In air brake tests of 1,196 trains departing from terminals last year, comprising a total of 41,846 cars, inspectors of the Bureau of Safety found but 6 non-air cars. There is no longer any lack of available equipment, and any failure to comply with the requirements of law must be ascribed to neglect of the condition of equipment.

In the terminal tests above referred to our inspectors found 330 cars with brakes cut out and 1,947 cars with inoperative brakes. It is a matter of common knowledge that these terminal tests on departing trains do not correctly disclose actual operating conditions, for the reason that when the presence of a government inspector is known more than usual care and diligence are exercised in inspecting and testing brakes, as well as in setting out or repairing cars with defective brake equipment. As a result, reports of such tests are misleading and indicate better conditions and practices than actually exist.

In order to obtain a check upon the true condition of air brake equipment in general, tests of trains upon their arrival at terminals have also been made during the past year. In some instances the contrasts between the condition of arriving and departing trains are extreme and striking; for example, in one yard from which trains were departing with 100 per cent operative brakes, trains were arriving with as low as 56 per cent operative brakes. Of course it is as much a violation of law to haul a train into a terminal as away from a terminal with less than the specified minimum percentage of operative brakes or with associated power brakes not used and operated. The law states that it is unlawful to "run any train on its line" without the specified equipment.

The fact that prosecutions have not generally been filed in the past, except in cases where trains have departed from terminals with inadequate brake equipment, does not alter the requirements of law. In connection with these arriving tests, it should be noted that they serve merely to disclose cut out or inoperative brakes; in the reports of these tests there is nothing to indicate whether or not the brakes classed as operative are in effective and efficient condition. Statistics for the first year based upon these arriving tests will not be complete until July, but the results will be set forth in the next annual report of the Bureau, and will probably be published in detail in order to show the actual condition of air brake equipment in use.

It goes without saying that the terminal air brake tests conducted by the railroads, both arriving and departing, should be much more comprehensive and thorough than the inspections and tests made by the government inspectors. The tests made by the government inspectors are designed merely to indicate the general condition of air brake equipment for the purpose of ascertaining whether or not the law is being complied with. No specific method of conducting tests of this nature is prescribed; it is left to the individual inspector to secure the required information, and methods followed vary with locations and operating requirements, as well as with personnel.

It is not my purpose in this paper to enter into a discussion in detail of the methods which should be followed in conducting terminal tests. The results accomplished by these

tests constitute the issue of paramount importance, and in each instance the results accomplished as reflected by the condition of air brake equipment should form the criterion by which effectiveness of methods in use is measured.

It is almost trite to say that inspections and tests should be made to ascertain whether all air brake parts and piping are in place, that foundation brake rigging is intact, and that all such apparatus is in operative condition. But it is frequently found in many parts of the country that the inspections and tests made are extremely superficial in character. It is not uncommon to find that no attention whatever is paid to broken retainer pipes or retainers missing or disconnected. Inspections have also indicated the necessity that more attention be devoted to the condition of foundation brake rigging. The need of better maintenance of this equipment is particularly apparent in view of the fact that the foundation brake rigging is an essential part of both the air brake and the hand brake equipment on a car and an inoperative hand brake is a penalty defect. It is the purpose of the Bureau of Safety in future to devote more attention to the condition of foundation brake rigging.

It hardly seems necessary to point out that tests made with yard-line pressure of 90 lb. when the train line pressure used is 70 lb., are not wholly desirable; nor that simply observing that the brake on the last car in a train applies and releases properly is not a proper test of the brake equipment of a departing train; but these conditions have been found to exist in large yards of important railroads.

It has been found that repair work was not being properly done. In one case in the middle west, one of the Bureau's inspectors made an air brake test on a train of 97 cars, in which the brakes on 17 cars were found inoperative, the majority of them being refrigerator cars. The triples on six of these cars bore stencil marks indicating that the triples had been cleaned within a month, but outward appearances led the inspector to believe that no work other than stencilling had been done on them. Subsequently an investigation was made at points where these triple valves had been stencilled and one triple valve was found newly stencilled that had not been cleaned; and on another newly stencilled car the dust collector was full of dirt and corrosion. In another case eight cars were found bearing stencil marks showing that brake cylinders and triples had been cleaned within the last three days. From outward appearances none of these cars had been worked on and three of them were taken down and examined. The brake cylinders and triples were found in a very dirty condition and the examination showed conclusively that no work had been done on them except stencilling. These conditions were traced to their source and corrective measures taken by officials in charge.

It is essential that air brake men be continually on the alert with a view of detecting and correcting improper maintenance and repair work resulting from ignorance, incompetence, lack of proper facilities, or slipshod methods.

In many locations tests which are intended merely to show that brakes are operative are insufficient to meet operating requirements; it is essential not only to have operative brakes, but also to make certain that the equipment is in effective operating condition, including foundation brake rigging, brake cylinder, triple valve, retaining valve and all piping. Inoperative and ineffective brakes combined have resulted in numerous violations of the air brake law on mountain grades. There are a number of mountain grades in various parts of the country upon which it is common practice to control trains by means of hand brakes, holding the air brakes in reserve and using them only in case of necessity or emergency to supplement the hand brakes. On some grades no other practice has ever been followed. The attention of the commission has been called to the situations in which these unlawful practices exist at various times and

for various specific reasons. In one case an accident resulting from a portion of a train running away on one of these grades was investigated by the Bureau of Safety, and this investigation disclosed that one of the conditions leading up to this accident was the use of hand brakes for the purpose of controlling the train. Proper maintenance of present equipment is all that is required to permit trains to be handled safely on these grades by means of power brakes. And it is in the terminals through which these cars pass en route to these grades that the greater part of this maintenance work must be done. Excessive leakage and defective retainers were among the prevailing conditions which required considerable attention.

The order of the Commission of June 6, 1910, requires that not less than 85 per cent of the cars of a train shall have their brakes used and operated by the engineer of the locomotive drawing the train, and that "all power-brake cars in every such train which are associated together with the 85 per cent shall have their brakes so used and operated."

The minimum percentage requirement of this order is generally understood and recognized, and it is an infrequent occurrence that a train is hauled from a terminal having less than 85 per cent of the cars equipped with power brakes in operative condition. But in addition to the minimum percentage requirement specified, there is also a maximum requirement; the order reiterates the provision of law that all power-brake cars in a train which are associated together with the specified minimum percentage shall have their brakes used and operated. Comparatively little attention has been paid to this maximum requirement, and the belief is widespread and general that if a train has the prescribed minimum percentage of power-brake cars with air brakes in operation, the terms of the law are fully complied with. It is common practice for trains to leave terminals having cars with inoperative brakes, or having brakes cut out, notwithstanding the fact that facilities are available at such terminals for making repairs or replacements necessary to place all power brake equipment in proper operative condition.

Strict observance of the associated car provision of the law, as applied to trains leaving terminals or other points where facilities for making repairs are available, would result in 100 per cent operative power brakes in practically all trains leaving such points. The adoption of this practice would inevitably result in general and material improvement in air brake conditions; careful and thorough air brake tests at terminals would be required, and prompt attention would necessarily be given air brake repairs. The number of violations of the minimum percentage requirement would also be reduced, for the reason that trains now frequently leave terminals with barely 85 per cent of the cars having power brakes in operative condition, and if the brake equipment on additional cars becomes defective en route, or if cars with defective brakes are picked up, or if cars having operative brakes are set out, the train then has less than the minimum of 85 per cent required. This practice would also go far toward meeting the complaint frequently heard that air brake maintenance is neglected on roads where braking conditions are less severe than on roads having steep mountain grades, thereby imposing an excessive burden on the air brake inspection and repair forces of the latter roads.

If required to do so in order to bring about necessary air brake improvements, the Commission can adopt a different policy in the administration of the air brake law, and the existing minimum percentage required can be increased. But it is to be hoped that the railroads themselves are fully alive to the needs of the present situation and will voluntarily take such steps as may be necessary. Proper action by the Air Brake Association and active co-operation of all concerned with these matters will undoubtedly go far toward forestalling necessity for further action in the matter by the Commission.

LOCATION OF BRAKE PIPE ENDS AT THE LOCOMOTIVE PILOT*

By W. W. Wood

Chicago, Indianapolis & Louisville

At the pilot of a locomotive a situation exists in which the recommended practice, as it concerns brake-pipe ends, cannot be adhered to successfully.

The extended pilot, formerly standard everywhere, would not permit the diagonal cross-carrying of the coupled hose when connected with a car ahead or the rear of a leading locomotive, if the pipe end was on the left side of the drawbar. For that reason the pipe ends are commonly found to the right of the drawbar. Here is a condition that provides a brake pipe without lateral deflection from rear to front of locomotive.

But the locomotive builders having located the pipe end 26 in. away from the M. C. B. standard point for cars, have fixed its height from the rail and the distances from the center line of the drawbar shank and pulling face of the coupler knuckle, the same as provided for cars; this brought the terminal angle-fitting too close to the angle cock of the car ahead. Most railroad shops are following this practice.

The result on the Monon was that when the air was coupled to a car ahead, both hose of the connected pair would be crimped and the passage of air restricted. On a double-headed passenger train the air signal and brake equipment of each engine had been tested and found in good condition before leaving the roundhouse. The air piping of the second engine was exactly as it came from the builders and the pipe terminals on the tender of the forward engine were approximately M. C. B. standard in location. After coupling-up, both pairs of hose, brake and signal were crimped so flat that the air signal on the leading engine could not be operated from the cars but would respond to discharges from the pilot hose. The brakes on the cars would apply on a service reduction from the leading engine, but with emergency test from the leading engine, service application only was obtained on the cars.

Recommended practice now extends the brake-pipe ends on certain classes of freight cars much nearer the line of the pulling face of the coupler knuckle than formerly. Two modern, steel freight cars coupled together have their connected hose couplings carried at an angle of 90 deg. to the center line of the car so that they couple exactly crosswise. If such a car were coupled to the pilot of an engine having pipe ends as usually found, the condition should be considered absolutely impossible.

When this subject was brought up at the Central Air Brake Club, some members argued that with the modern receded pilot it would be possible to locate the brake-pipe ends at the left of the drawbar and follow the M. C. B. specifications as to location throughout. This will not hold good on all engines. On the Monon it has been found to be an easy matter to keep the pipe lines on the right of drawbar and obtain an ideal line-up of the hose when coupled forward.

Experimentally, we coupled a locomotive to the rear of a tender having standard pipe-end locations, detached the hose and angle fitting from the brake pipe at the pilot, connected its coupling with that of the tender and screwed a short piece of pipe into the other opening of the angle fitting to represent the brake pipe. Laying this piece of pipe directly on top of the pilot beam and placing its center 13 in. from the center line of the coupler shank, the ideal location was found. In practice we turn the angle fitting slightly toward the center of the track, about 20 deg. from a vertical line through the brake pipe. No attempt was made to standardize this location until we found that it would apply to every class of engine in service on the road.

*Submitted by the Western Air Brake Club.

This might not happen in all cases and the writer recommends that the car piping standards should be generally disregarded in the installation of pipe terminals at the pilot, and the proper locations at the right of the drawbar found for each class of engine.

Discussion

A number of variations in the location of angle cocks and brake pipe ends at the front ends of locomotives were brought out in the discussion. Much difficulty seems to have been encountered in arriving at a satisfactory location of the cut out cocks to meet the requirements of safety and, especially in passenger service, the convenience of the crew when doubleheading. The subject was referred to a committee for investigation and the drafting of a proposal for adoption as recommended practice for the location of brake pipe ends and the location and style of cocks to be used, at the next convention.

AIR SIGNAL VALVE MAINTENANCE*

By James Elder

From the writer's observation air signal valves have not been repaired and maintained as they should be, because air signals failed to respond from rear end cars or gave repeat signals. Where air signal valves are repaired so that they will pass the tests specified they will give good service for the entire period the locomotive is out of the back shop, with the possible exception of renewing the diaphragm. Thus the expensive practice of roundhouse men to keep tinkering with air signal apparatus would be greatly reduced. With the exception of changing a ruptured diaphragm, no other repairs to signal valves should be attempted in roundhouses or small shops. It is needless to say that a sufficient quantity of good repair or new signal valves should be obtained and be accessible for exchange purposes.

The important back shops should be supplied with suitable, inexpensive test racks, to represent the volume and

valves are (a) worn fit of stem and guide bushing, (b) bearing fit of stem in bushing carelessly destroyed by inexperienced workmen, either reducing the stem bearing with a file or mashing it in a vise while holding it to remove the diaphragm; (c) removing the projection at the lower end of the stem by filing it away, (d) facing off the seat at the upper side of the lower cap nut, (e) the use of inflexible diaphragms other than those made especially for signal valves.

The drawing shows the testing device used on several western railways. Any signal valve passing this device can reasonably be expected to operate properly on long passenger trains.

A careful analysis shows that the fit of the stem in the bushing is required to be accurate; that if the stem is too loose the valve will repeat or not give any signal at all; whereas, if the stem is too tight a fit in the bushing, the signal will be too long or be too sensitive to light leakage reductions. The following procedure should be followed in testing the valves, the feed valve being set to maintain 45 lb. pressure and the check valve spring in the combined strainer and check valve reducing the pressure 3 lb.:

Test No. 1—With the whistle valve applied and the system fully charged, open the car discharge valve until the whistle sounds, and then quickly allow the discharge valve to close. As soon as whistle stops blowing quickly open the discharge valve again and so on, in this manner obtaining short blasts of the whistle in quick succession. Five distinct single blasts of the whistle should be obtained in 10 seconds, the time being measured from the instant of first opening the discharge valve, until the instant of opening it for the fifth time. Inability to obtain the five blasts within this time indicates excessive friction between the valve stem and bushing caused by a too close fit.

Test No. 2—With the system fully charged, hold the discharge valve open for 15 to 20 seconds continuously. This should produce one continuous blast of the whistle lasting until a few seconds after the discharge valve is allowed to close. If several short blasts of the whistle are obtained in the test, it indicates that the fit between the valve stem and bushing is too loose.

Discussion

The discussion indicated a general agreement with the author of the paper as to the inadvisability of making repairs to the signal valve in the roundhouse, most of those speaking even condemning the practice of changing diaphragms. The practice of many roads is to return the signal valve to the manufacturer for repair, but it was pointed out that because of the inability to have every valve taken care of in this way, the work done on those handled on the road was likely to suffer because of the lack of proper facilities for doing the work. The inference was that better results would be obtained if each road provided facilities at its principal shop for repairing these valves and handled them all at that point. The difficulty which in some cases has been experienced with rust which accumulates around the valve and its spindle and interferes with its satisfactory operation was mentioned. In the opinion of several members the best solution of this difficulty is to locate the signal valve at a point high enough in the cab to prevent the accumulation of moisture.

Air Consumption of Locomotive Auxiliaries

The committee reporting on this subject through wide investigation has determined that these devices are generally wasting much compressed air. A simple code of tests and condemning limits was proposed, the observance of which may be expected to result in materially improving conditions. An abstract of this report will be found on another page in this issue.

TERMINAL BRAKE WORK FROM THE REVENUE STANDPOINT*

By C. C. Ferguson

General Air Brake Instructor, Great Northern

The investment in all that constitutes a railway is earning just so long as cars are moving toward their destinations. When they are not, it is losing, because interest, wages and

Rack for Testing Signal Valves In Railroad Shop

resistance of a 15-car passenger train, so that signal valves can be tested while locomotives are passing through the back shops, and no signal valve should be returned to any locomotive if it fails to pass the tests prescribed.

The greatest advantage will be gained by doing extensive repairs to signal valves at only the main shops. When signal valves are found worn or out of standard, and heavy repairs are required to put them in shape, and the valves cannot be repaired so they will pass satisfactorily, it will be to the advantage of the railway to send them to the manufacturer and have them restandardized.

Some of the troubles incident to poor operating signal

*Submitted by the Central Air Brake Club.

*Submitted by the North-West Air Brake Club.

other necessary expenses are going on. This means that switching, testing air brakes, repairing and other work in terminals are losing revenue. Such delays are necessary, but it is plain that they should be kept as low as possible. The problem is now to test and make necessary repairs in the least time and with the minimum of switching.

Attention is directed to the instructions on Test and Repairs to Brakes on Cars in Terminal Yards, recently made recommended practice by the American Railroad Association, Section III-Mechanical. These instructions are as follows:

INCOMING TRAINS

1. Freight cars in terminal yards should have the air brakes tested as follows:
2. Freight trains, on arrival at terminals where inspectors are stationed to make immediate brake inspection and repairs, shall have slack stretched and left with brakes fully applied in service application. Inspection of brakes should be made as soon thereafter as practicable and any needed repairs made, or promptly mark for repair tracks any cars that cannot otherwise be repaired.

OUTGOING TRAINS AND YARD TESTS

3. While the train is being charged, make a visual inspection of retaining valves and retaining valve pipes, position of angle cocks and hose, and examine closely for leaks from the brake pipe and its connections, and make necessary repairs to reduce this leakage to a minimum when the brake system is charged to standard pressure.
4. When the brake is charged to standard pressure, make a 15-lb. service reduction, after which a second examination of the train should be made to determine:
 - (a) Brake pipe leakage.
 - (b) If triple valve will operate on service application.
 - (c) Piston travel.
 - (d) Brake cylinder leakage.
 - (e) If the brakes release properly.
5. If, during this test, the brake pipe leakage, as indicated by the brake pipe gage, exceeds 8 lb. per minute, it should be reduced to 8 lb., preferably 5 lb., and if piston travel is less than 6 in. or more than 8 in. it should be adjusted to 7 in. All defects found shall be repaired in the yard or car sent to shop or repair track for necessary attention.
6. In addition to the above terminal tests, at last terminal inspection point prior to descending mountain grades, it must be known that a sufficient number of retaining valves are in good operating condition to control the train.

The Incoming Test

Normally and properly the first thing done to an incoming freight train is to make the general inspection. Here we have dead time that, by means of incoming brake test, should be utilized to locate air brake defects so that such as are heavy may be marked for the repair tracks before switching is done and all available time employed for repairing the others.

But the time and a half for overtime since allowed to freight train men, and insufficient consideration given to certain features of the recommended practices warrant some changes in the foregoing.

Several of the roads represented in the North-West Air Brake Club have long since demonstrated the practicability and value of the incoming brake test. In fact, the Soo Line is undoubtedly the pioneer in making this test, with the Northern Pacific a close second. This is mentioned merely that due weight may be given to recommendations based on long experience. The first recommendation is that paragraph 2 in the foregoing be changed to read as follows:

2. The incoming air brake test should be made with all arriving freight trains and transfers, and to permit of this the incoming crews shall leave the brakes fully applied from standard pressure by a service reduction or reductions totaling 20 lb. Inspection of the brakes should be begun immediately and completed within 20 minutes, confining it to observance of piston travel, brakes that do not apply or that leak off and to other observable leakage, and quickly indicating defects found by suitable chalk marks. On completion of this inspection make indicated repairs or mark cars for the repair tracks, as the circumstances require.

The advantage of having the slack stretched while inspecting draft rigging and air hose is recognized, but to do this in an effective way will require, after the stop, releasing the air brakes, applying rear hand brakes, pulling out the slack, fully recharging and reapplying the air brakes, and an attempt to include it would increase the amount of overtime and would decrease the reliability of the incoming brake test.

The present reading of paragraph 2 discourages the incoming test, first, by the qualification, "where inspectors are stationed to make immediate inspection and repairs"; and, second, by stating that, following the application of the

brakes, inspection "should be made as soon thereafter as practicable." This inspection is mainly to determine whether the brakes are reasonably efficient, and it will assuredly be granted that a brake which has not leaked off in 20 minutes will meet with this requirement. To appreciably extend this inspection time is unwarrantedly to delay traffic and increase expense, as it will send cars with reasonably efficient brakes to the repair tracks. The alternative is that inefficient brakes will not be detected.

Should it be desired to provide for the alternative of an incoming brake test being made by the slower and more cumbersome use of a yard testing plant, which we do not favor here, it should be cared for by a separate paragraph.

The recommended change in paragraph 2 refers to "standard pressure," understood for freight to mean 70 lb., and attention is called to the fact that if the test is made from a higher pressure it will pass some defective brakes as satisfactory because of the greater amount of auxiliary reservoir air to be leaked away. Hence, if any road is using a higher brake pipe pressure on any moving trains, it is recommended that it be reduced to 70 lb. (by applying and releasing) before making the test application.

The Outgoing Test

The haste more or less incident to the outgoing terminal brake test referred to in paragraph 4 will often result in the application being made before some brakes are fully charged. Hence, a reduction of 15 lb., with long trains, will result in some brakes failing to apply or hold long enough for the inspection which would be found satisfactory if they had been charged or if the reduction had been 20 lb.

The desire to combine with this test a fairly satisfactory measure of the rate of brake pipe leakage is appreciated and no recommendation for a change is made at this time.

Clause (e) is a detail which cannot be determined while brakes are applied, as here stipulated. While the object will doubtless be generally understood, the wording of this paragraph could advantageously be changed to make the meaning clearer.

R. H. Aishton's circular 95 of January 8, 1920, dealing particularly with avoiding delays at terminals, in order to lessen time and a half for overtime, suggests for each important yard the need of a yard plant for testing the outgoing train before the engine is applied. This is approved, but with the distinct understanding that it cannot accomplish the needed results unless the incoming test is made; also, that to realize its value sufficient inspectors must be available who must receive prompt notice when a train is ready for them, so as to avoid wasting time waiting for it to be made up or being late because of not knowing it was ready for them. This is not the time nor the place to make other than the lightest repairs, mainly stopping brake pipe leaks. In fact, if the incoming test and indicated repairs have been made as they should be and if inspectors are promptly advised when each train is made up, the character of the remaining work, including the outgoing terminal brake test, will usually be such as to enable the despatcher to figure quite accurately as to when a train will be ready. The outgoing crew would then find the train tested and charged and requiring no more brake work on their part than making the brake pipe test from the engine immediately after attaching it. If operating departments really propose to provide and make use of outgoing yard brake charging and testing plants, it would be well to add to the recommended practice instructions to cover their use.

As the detailed instructions governing the making of the incoming brake test can largely influence the results obtained we submit the following as in effect on one large road: "Enginemen and trainmen of freight trains on arrival at terminals will leave the brakes applied by a 20 pound service reduction made from 70 pounds. Where

engineman has made an automatic application for stopping he will as soon as stopped, add to it by one farther, continuous reduction sufficient to make a total of 20 pounds, and watching the gage, insure that this amount is had when the brake valve discharge ceases. On its completion he will give one short whistle blast as advice to brakeman that he may cut off and to inspectors that inspection may begin. The brakeman will not close angle cocks until this signal is given.

"When the train must be left on two or more tracks, or when crossings must be cut, those concerned will follow the foregoing plan before cutting off each part.

"To avoid preventing inspectors from ascertaining the condition of air brakes, switchmen, carmen and others must not discharge any air from the auxiliary reservoirs or brake pipe of cars that have not been inspected. Before discharging any air from those already inspected an angle cock must be closed between such and any uninspected brakes.

"On brakes being applied, as indicated by whistle signal, inspectors will at once and rapidly examine for piston travel, brakes failing to apply, any that have leaked off and brake pipe leaks. At this time, make no repairs; merely indicate the defects with chalk. After completing inspection repair the defects that should be cared for in the yard. For other defects bad-order cars for repair tracks, unless impracticable, as may be with time freight. The air brake and the general inspection must not be made by the same man or men.

"Adjust incorrect piston travel (less than 6 inches or over 8 inches) to 7 inches. Consider cars over 12 months since brakes were cleaned as having defective brakes. Loads that cannot be held for brake repairs earlier will, where destination is a terminal, be marked on arrival "BO when empty," with date, and defect. These will be delivered to repair tracks as soon as practicable after unloading."

Discussion

The discussion covered the whole field of freight brake conditions, which all have a bearing on the difficulties of getting trains out of terminals with brakes in condition to meet the requirements of the safety appliance law without excessive terminal delays. The discussion indicated clearly that freight brakes generally are in an unsatisfactory condition from the service standpoint and that this condition is not due to any one cause, but to a large number of causes. Some of the causes mentioned were undesired emergency brake applications, excessive brake pipe leakage, careless and unskilled workmanship in maintenance, neglect of maintenance, inadequacy of the customary type of attachment for brake cylinders and auxiliary reservoirs, retention in service of worn-out brake cylinders in which tight packing leathers are an impossibility and a lack of appreciation and indifference of the managements to the resulting loss in operating efficiency. That a high standard of brake maintenance is not only possible but practicable was indicated by the experience of several roads operating with a high percentage of their own equipment which is retained and maintained at home. Several instances were given where railroads regularly send trains, in some cases with as many as 90 to 100 cars, from terminals with not more than two or three pounds per minute brake pipe leakage, and one instance was mentioned where such a train, departing from the initial terminal with a leakage not to exceed three pounds per minute, arrived at the end of a 125-mile run and when tested showed but four pounds per minute brake pipe leakage.

That when once placed in good condition, the maintenance of a high standard of freight brake conditions is not a difficult matter was evidenced by the experience of the Duluth, Missabe & Northern, which was mentioned several times by members from other roads as having exceptionally good brake conditions. With a total of 7,000 cars in regular freight service on this line, it was necessary to set out on account of brake conditions but four cars in a period of

twelve months, and these were due to leaky cylinder packing leather caused by over travel of the piston in connection with a failure of the foundation brake gear. From an initial brake cylinder leakage of three pounds per minute, 2,000 cars after 24 months' service without cleaning had developed cylinder leakage not exceeding four pounds per minute maximum. Other roads reported as high as from 10 to 20 per cent of the brakes tested requiring recleaning in from one to three months following the last cleaning date.

The inability of the Air Brake Association alone to remedy these conditions because of the possible terminal delays and initial expense required to bring about a countrywide improvement of these conditions, was touched on several times. The value of the incoming test in this connection was dwelt upon because of the possibility of reducing terminal delays chargeable to brakes by utilizing the dead time during the general inspection of the train to make needed repairs. A significant point was brought out in connection with the establishment of the incoming test on one road where it has been in effect for a number of years. Some difficulty had been experienced in convincing the management of the desirability of the test, as the time available resulted in doing much more work than is usually permissible following the outgoing test. It was found, however, that an appreciable credit balance resulted from the charges against other roads for the extra amount of work done, and the presentation of this fact to the management secured approval for the establishment of the incoming brake test.

The convention voted to refer the subject to a committee with instructions to investigate general conditions, formulate recommendations and present data as to possible savings from a revenue standpoint from the establishment in practice of the recommendations.

Other Papers and Addresses

The St. Louis Air Brake Club submitted a report on "Changes in the H-6 Brake Valve," signed by W. H. Davies, R. E. Wark, and F. V. Johnson, which outlined a method of making the changes in existing brake valves that are now incorporated by the manufacturer in new valves. An illustrated lecture on "Modern Trains and the U. C. Equipment," by J. C. McCune, was submitted by the Manhattan Air Brake Club.

During the course of the convention, the association was addressed briefly by W. H. Winterrowd, chief mechanical engineer of the Canadian Pacific, and F. W. Brazier, assistant to the general superintendent of rolling stock, New York Central. R. I. Cunningham of the Westinghouse Air Brake Company, gave a very interesting talk on air brake conditions in France.

Business

An invitation from the American Railroad Association, Section III-Mechanical, to affiliate as a division of that organization was brought before the association and referred to a committee, which drafted a tentative set of by-laws designed to protect the interests of the association membership as it is now organized, in the event of affiliation. The matter was finally referred to the executive committee with instructions to conduct negotiations with Section III-Mechanical and report to the association at the next convention for action by the members.

The following officers were elected for the ensuing year: President, L. P. Streeter (Illinois Central); first vice-president, Mark Purcell (Northern Pacific); second vice-president, George H. Wood (A. T. & S. F.); third vice-president, E. M. Kidd (Norfolk & Western); secretary, F. M. Nellis (Westinghouse Air Brake Company); treasurer, Otto Best (Nathan Manufacturing Company). W. W. White (Michigan Central) was elected a member of the executive committee to fill the vacancy created by Mr. Kidd's election as third vice-president.

View of Inspection Shed and Accumulated Car Wheels

ECONOMIES POSSIBLE BY CAR WHEEL GRINDING

The Field for Effective Car Wheel Grinding Includes New and Old Cast Iron and Steel Wheels

WHILE an exhaustive study of car wheel grinding is impossible within the limits of this article, certain convincing data are presented which proves the possibilities of the practice. Not only have cast iron wheels with slid flat spots been reclaimed by grinding, but important railroads in different parts of the country have found it profitable to grind the treads of new cast iron and cast steel wheels, these being used in light passenger service and

reclaimed by grinding, any railway shop can afford the installation of a grinding machine, provided enough slid flat wheels come to that point to keep the machine busy eight hours a day. In case enough slid flat wheels are not available, the machine can be kept busy grinding new wheels.

The car wheel grinding practice most commonly known consists of grinding flat spots out of chilled cast iron car wheel treads. Obviously, the thickness of chill is greater on a new wheel than on one with a heavy mileage, and the length of flat spot that can be ground out without getting through the chill is, therefore, relatively greater. The minimum depth of chill at the middle of the tread of a good quality wheel is $\frac{1}{2}$ in. and, while common practice limits the length of flat spots removable by grinding to $3\frac{1}{2}$ in., some authorities maintain that this limit should be increased to 4 in. or 5 in. On a 33-in. wheel, $3\frac{1}{2}$ -in. and 5-in. flat spots represent depressions of .095 in. and .190 in., respectively, which leaves a considerable depth of chill after grinding. The kind of flat spot removable by grinding is shown in Fig. 1, while Fig. 2 shows a pair of wheels after being ground.

In addition to reclaiming cast iron wheels with flat spots, it has proved desirable to grind cast iron passenger car wheels when newly applied and before being put into service. One of the leading railroads in the east has followed this practice for a considerable period of time and finds that when the tread of a wheel is once ground smooth, round and concentric with the journal, there is a material increase in the actual ton mileage. In addition, flange wear is reduced to a minimum by having true wheels of equal diameter on the same axle. For suburban passenger service especially, ground wheels are desirable because the treads are then concentric with the journals, and the whirring sound due to raised chill marks is eliminated.

While most roads turn their wrought steel tired wheels, grinding presents a possibility of saving service metal because it is not necessary to take a heavy cut to get under the hard skin on the treads. The controlling feature as to grinding or turning wrought steel wheels with flat spots is

Fig. 1—Type of Flat Spot Removable By Grinding

under light weight box cars, refrigerators and caboose cars.

Besides the need for a more general installation of car wheel grinders in railway shops, it is apparent that those machines already installed should be used to their utmost capacity. In fact, the crux of the matter lies right there. With a net profit of \$6.05 on every pair of cast iron wheels

the condition of wear of the flanges. With the cast steel wheel, however, especially one with a high proportion of manganese in the tread, the car wheel grinding machine affords the only means of securing a smooth wheel tread without eccentricity.

An example of the type of machine developed for car

Fig. 2—Car Wheels Just After Being Ground

wheel grinding is illustrated in Fig. 3. It can be used to grind car wheels up to 44 in. in diameter, and engine truck wheels up to 36 in. in diameter. Since the wheels are ground without being removed from the axle, the machine is designed for standard 4-ft. 8½-in. gage, and cannot be changed for other gages. Two grinding wheels of 24-in. diameter and 2¾-in. face are used with the machine, and are adapted to grind either steel or chilled cast iron wheels. Driven by a 35-hp. constant speed motor, the machine has ample power to remove metal quickly, and the production is materially increased by a pump and water tank arrangement, furnishing 40 gallons of water per minute on grinding wheel.

Chilled Cast Iron Wheels

The number of chilled cast iron car wheels reclaimed by grinding at any one point varies greatly from time to time and with the season of the year. For example, it has been noticed that much more slipping, with resultant flat spots, occurs during the winter months than during any other time of the year. The number of flat spots developed during the spring and summer months, however, is large. In March of the present year, 1,200 cast iron wheels were sent to the scrap dock of the eastern railroad previously referred to, and 10 per cent of these were reclaimed by grinding. It is felt that many shops not now equipped with car wheel grinding machines are unable to take advantage

of a large possible saving. While interchange rules do not provide for the removal of wheels with flat spots under 2½ in. long, a large number of flat spots over that length develop. In addition, a careful inspection of the scrap pile indicates that inspectors are condemning many wheels that could be reclaimed by grinding.

TABLE I—TIME REQUIRED TO GRIND FLAT SPOTS OUT OF CHILLED CAST IRON CAR WHEELS

Car wheel, pair, No.	Time of set up, minutes	Grinding time, minutes	Total, minutes
1	10	30	40
2	10	39	49
3	10	17	27

25	10	16	26
26	10	50	60
27	10	35	45
28	10	37	47
29	10	30	40
30	10	40	50

Average time = 38 minutes

To estimate the actual saving effected by grinding out the flat spots in chilled iron car wheels, the data shown in Table I were obtained in a trial test. The average time of setting up the pair of wheels in the grinder was 10 minutes,

Fig. 3—Machine Developed for Grinding Mounted Car Wheels

and the grinding time varied from about 14 to 50 minutes, depending upon the condition of the wheel tread and the length of the flat spot. As indicated, the average total time required to grind each of 22 pairs of wheels was 38 minutes.

The saving effected, as shown in Table II, was computed by obtaining the difference between what it would cost to apply a new wheel and the cost of grinding flat spots out of the old one. It is obvious that the cost, in the case of a new wheel with a newly developed flat spot, includes the difference between its new and scrap value, plus the cost of removing, boring and applying the new wheel. This total figure is \$7.55, as indicated. Most manufacturers offer a

TABLE II--SAVING EFFECTED BY GRINDING FLAT SPOTS OUT OF CHILLED CAST IRON CAR WHEELS

Cost of applying new wheel:	
M. C. B. differential on 33-inch wheel.....	\$7.25
Charge for removing old wheel.....	.09
Charge for boring new wheel.....	.12
Charge for pressing on new wheel.....	.09
Total	\$7.55
Cost of grinding out flat spots:	
Labor per pair, at .72 an hour.....	\$0.46
Power per pair, at .02 a kw. hour.....	.28
Grinding wheels, per pair.....	.15
Interest at 6 per cent.....	.23
Depreciation and repairs at 10 per cent.....	.38
Total	1.50
Total saving per pair.....	\$6.05

differential of \$1.05 per hundred pounds, but in the present calculations the M.C.B. differential of \$7.25 for a 33-in. wheel is used. The labor charges represent a relatively small proportion of the total, and the total figure is conservative, because of the assumption that only one wheel develops a flat spot, whereas the more common experience is to find a flat spot on both wheels mounted on the same axle. The saving will of course vary with the probable service life of the wheel depending on the amount of tread or flange wear existing at the time the flat spot develops.

The first item to consider in the cost of grinding out flat spots is the labor charge. As shown in Table I, the average

TABLE III--TIME REQUIRED TO TRUE UP NEW CAST IRON WHEELS BY GRINDING

Car wheel, pair, No.	Time of set up, minutes	Grinding time, minutes	Total, minutes

19	10	9	19
20	10	10	20
21	10	9	19
22	10	8	18
Average = 19 minutes			

time required for grinding, including the time necessary to place the car wheels in the machine, is 38 minutes. In most shops the man who operates this types of machine receives 72 cents an hour, which, for a period of 38 minutes, is 46 cents. It is estimated that the machine at normal load consumes about 30 kw. at a rate of two cents a kw. hour, but the power is not on during the time of setting up. Therefore, the total cost of power per pair of wheels is:

$$38 \div 60 \times 2 \text{ cents, or } 28 \text{ cents per pair.}$$

A very important item in operating efficiency is the selection of a suitable grinding wheel. It is possible that a certain grinding wheel can be chosen, which will grind as many as 800 wheels, but the results both as to production and quality of work are not nearly as satisfactory as when a

softer grade of wheel, which will grind possibly 200 wheels, is used. If grinding wheels cost practically \$30 a piece and last to grind 200 wheels, the cost of grinding wheels per pair of car wheels ground is 15 cents, as shown.

Interest charges at six per cent per annum on an investment of \$15,000 (the cost of the machine) amount to 23 cents per pair of wheels. This figure is obtained by assuming an eight-hour day, and a time of grinding of 38 minutes. It is obvious that a high priced machine must be kept busy as much as possible to reduce the overhead charges, and in shops which are working two shifts, the interest charge on the investment is reduced one-half.

The depreciation and repair charges, shown in Table II, are estimated on a 10 per cent per annum basis and amount to 38 cents per pair of wheels. The total cost of grinding, then, amounts to \$1.50 per pair of wheels. This cost is nearly three times as great as that computed on page 406 of the 1917 volume of the *Railway Mechanical Engineer*. Attention is called to the relatively large proportion of the charges for interest and depreciation, elements which are too often neglected in estimated savings. With the present cost of modern up-to-date machinery, these items must be carefully considered and every effort made to use the machines to their utmost capacity; otherwise, it is impossible to show a net profit in operation. Inasmuch as the cost of shipping flat wheels to the grinder will about equal the cost of shipping new wheels, the total saving for each new wheel is \$6.05, as shown in Table II, and the only requirement necessary to make a car wheel grinder earn a profit is to see that sufficient wheels are received to keep the grinder busy eight hours a day.

New Cast Iron Wheels

The idea of grinding new cast iron passenger car wheels on the tread to insure the treads being accurately round and concentric with the journals, has been tried and proved good practice. When new wheels are ground in this way, there is an error not exceeding .002 in. or .003 in. from a perfect circle, and this insures a smooth riding wheel on which the brake shoe is not likely to stick. The grinding times on a

TABLE IV--DATA SECURED IN GRINDING NEW CAST STEEL CAR WHEELS

Diameter of grinding wheel, inches	Car wheel size, inches	Depth of cut, inches	Net grinding time, minutes

17 1/4	36	.070	2.32	
	36	11.50	
Average time = 8.62 minutes				

lot of 22 new chilled cast iron passenger car wheels are shown in Table III. As in the previous tests, the time of set-up is estimated at ten minutes and the total average time of grinding is nineteen minutes.

Inasmuch as the benefits of grinding new car wheels are nearly all indirect, there is no good method of estimating the saving, but several important roads have given the practice a thorough try-out and found it economical in the long run and satisfactory. Thus far very little grinding of car wheels, except in the passenger department, has been done.

New Cast Steel Car Wheels

In the grinding of steel car wheels, new factors enter into consideration. For example, steel tired wheels can probably be placed in a wheel lathe and turned at a cost not much greater and in no longer time than would be required to grind the wheel treads. A new flange contour would be obtained but at the expense of service metal since a grinding machine does not need to cut under the hard surface skin on the tread. With the cast steel car wheel, however, especially one having a manganese tread, the pendulum again swings in favor of the car wheel grinding machine as a method of truing the wheel tread and making it both round and concentric with the journal. Attention is called to Table IV, which shows the data secured in grinding 25 pairs of steel wheels. The average grinding time was 8.62 minutes, which, added to 10 minutes, the time of set-up, gives a total time of 18.62 minutes. In other words, there is little difference in the length of time required to grind either the cast iron or cast steel car wheel. Additional information secured in this test shows the reduction in grinding wheel diameter as the work progressed, also the depth of cut which varies from .043 in. to .150 in.

Conclusion
